- What kinds of contracts might reduce that uncertainty?
- What would be the premium for a contract that…
  - Pays restaurant servers when they're stiffed on the tip?
  - Pays lawyers when they lose a case?
  - Pays academics when they're rejected from journals?

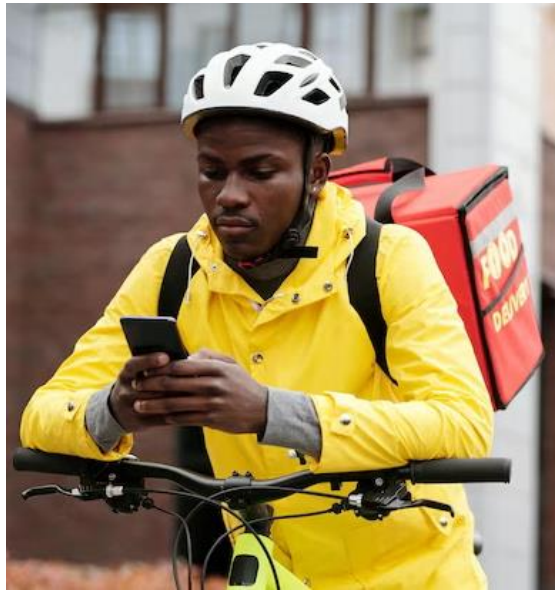

Insuring Labor Product

- Most workers' labor product depends on uncertain factors
- What kinds of contracts might reduce that uncertainty?
- What would be the premium for a contract that…
  - Pays restaurant servers when they're stiffed on the tip?
  - Pays lawyers when they lose a case?
  - Pays academics when they're rejected from journals?
- Employers provide *implicit insurance* through **fixed wages**

Piece-rate Pay

- Paid by unit of output
- Worker sells labor product at market price
- Examples:
  - Rideshare driver paid per mile
  - Self-employed freelance photographer

← Earnings Risk Insurance →

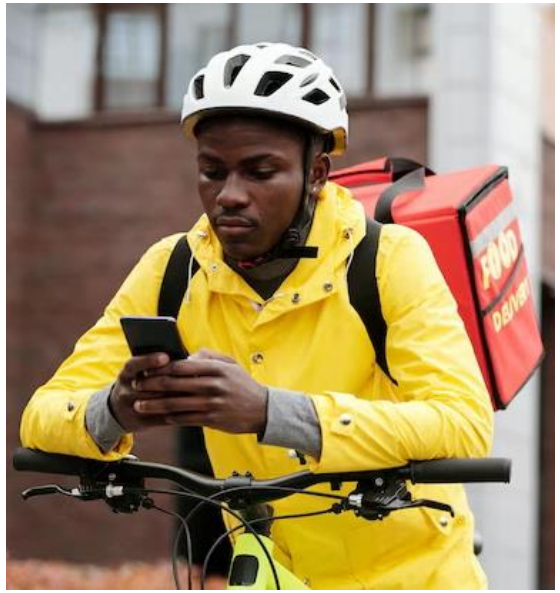

Piece-rate Pay

- Paid by unit of output
- Worker sells labor product at market price
- Examples:
  - Rideshare driver paid per mile
  - Self-employed freelance photographer

Fixed Wages

- Paid by unit of time
- Worker sells *claim* on labor product
- Examples:
  - Limo driver paid per hour
  - Staff photographer with annual salary

← Earnings Risk Insurance →

Piece-rate Pay

- Paid by unit of output
- Worker sells labor product at market price
- Examples:
  - Rideshare driver paid per mile
  - Self-employed freelance photographer

Fixed Wages

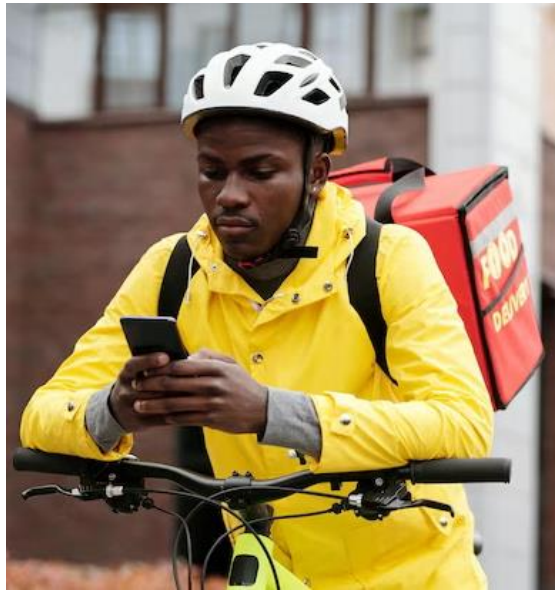

- Paid by unit of time
- Worker sells *claim* on labor product
- Examples:
  - Limo driver paid per hour
  - Staff photographer with annual salary

← Earnings Risk Insurance →

Hourly wage + tips

Base pay + commission

Annual salary + bonus

Are these contracts socially optimal?

Piece-rate Pay

- Paid by unit of output
- Worker sells labor product at market price
- Examples:
  - Rideshare driver paid per mile
  - Self-employed freelance photographer

Fixed Wages

- Paid by unit of time
- Worker sells *claim* on labor product
- Examples:
  - Limo driver paid per hour
  - Staff photographer with annual salary

Earnings Risk Insurance

Asymmetric information ⇒ market distortions:

- **Moral hazard:** fixed wage induces less effort
- **Adverse selection:** less productive workers sort into fixed wages

⇒ Suboptimal wage contracts

Piece-rate Pay

- Paid by unit of output
- Worker sells labor product at market price
- Examples:
  - Rideshare driver paid per mile
  - Self-employed freelance photographer

Fixed Wages

- Paid by unit of time
- Worker sells *claim* on labor product
- Examples:
  - Limo driver paid per hour
  - Staff photographer with annual salary

Earnings Risk — Insurance

Asymmetric information ⇒ market distortions:

- **Moral hazard:** fixed wage induces less effort
- **Adverse selection:** less productive workers sort into fixed wages

⇒ Suboptimal wage contracts

Public policies can mitigate these distortions:

- Taxes on tips, commissions, or bonuses
- Hourly wage subsidies
- Employment classification rules
- Portable benefits programs
- Minimum wage

⇒ Promote implicit insurance in wage contracts

Piece-rate Pay

- Paid by unit of output
- Worker sells labor product at market price

How do moral hazard and adverse selection influence wage contracts?

This Paper:

1. Experimentally identify treatment effects and selection into hourly pay
   - Two-stage RCT separates moral hazard, adverse selection, and wage effects
     1. Offer workers a *choice* between randomized hourly wage or piece rate
     2. Randomly increase hourly workers' wages to match highest wage offer
   - Find evidence of both moral hazard and adverse selection into hourly wages
     - MH ≡ Treatment effect: take-up of hourly contract ⇒ output ↓ by 8.7% relative to the mean
     - AS ≡ Selection into treatment: wage offer ↑ by 10% ⇒ marginal worker's productivity ↑ by 1.9%

       (2nd stage top-ups ⇒ estimates are independent of potential wage effects)

This Paper:

1. Experimentally identify treatment effects and selection into hourly pay

2. Develop model of fixed-wage labor markets under asymmetric info
   - Clarifies roles of AS and MH in shaping equilibrium, allowing for monitoring costs
   - Equilibrium and efficient shares of hourly work are determined by three curves:
     1. $\bar{w}(\theta)$: **reservation wage** for an hourly position at quantile θ
     2. $MV(\theta)$: **marginal value** of output among workers at a given reservation wage
     3. $AV(\theta)$: **average value** of output among workers with lower reservation wage

This Paper:

1. Experimentally identify treatment effects and selection into hourly pay

2. Develop model of fixed-wage labor markets under asymmetric info

3. Use MTE framework to estimate equilibrium and efficient hourly wages
   - Let experimental wage offers serve as **instrument** for hourly contract take-up ⇒
     - Hourly labor supply at given wage, $S(w)$ = propensity score
     - Marginal value under hourly pay, $MV_1(\theta)$ = potential outcome in treated state
     - Marginal value under piece rate, $MV_0(\theta)$ = potential outcome in untreated state

   ⇒ MTE of hourly contracts map directly into model

This Paper:

1. Experimentally identify treatment effects and selection into hourly pay

2. Develop model of fixed-wage labor markets under asymmetric info

3. Use MTE framework to estimate equilibrium and efficient hourly wages

4. Calculate DWL of inefficient wages and welfare impact of tax/subsidy
   - Underprovision of fixed-wage jobs ⇒ Welfare loss of $0.05 per worker hour

     ⇒ Annual loss among online clerical/data-entry workers ≈ $1.6 billion globally
   - Piece-rate tax ≤ 18% ⇒ raises $1 of govt revenue at social cost of $0.88 or less

     ⇒ *Eliminating* taxes on output-based pay (e.g., tips) likely has low social returns!

Existing Literature

5. **Extensions**

Detecting Moral Hazard and Adverse Selection

- Suppose worker i is offered a choice:
  - Remain on piece rate ($H_i = 0$)
  - Switch to an hourly wage ($H_i = 1$)
- Potential outcomes:

  Y_{1i}: Worker i's potential output under hourly wage

  Y_{0i}: Worker i's potential output under piece rate

$$Y_i = H_i Y_{1i} + (1 - H_i) Y_{0i}$$

Detecting Moral Hazard and Adverse Selection

- Suppose worker i is offered a choice:
  - Remain on piece rate ($H_i = 0$)
  - Switch to an hourly wage ($H_i = 1$)
- Potential outcomes:

  Y_{1i}: Worker i's potential output under hourly wage

  Y_{0i}: Worker i's potential output under piece rate

$$Y_i = H_i Y_{1i} + (1 - H_i) Y_{0i}$$

- Comparing across self-selected groups combines treatment and selection:

$$E[Y_i|H_i = 1] - E[Y_i|H_i = 0] =$$

$$\underbrace{E[Y_{1i} - Y_{0i}|H_i = 1]}_{\text{Treatment on the Treated}} + \underbrace{E[Y_{0i}|H_i = 1] - E[Y_{0i}|H_i = 0]}_{\text{Selection on } Y_0}$$

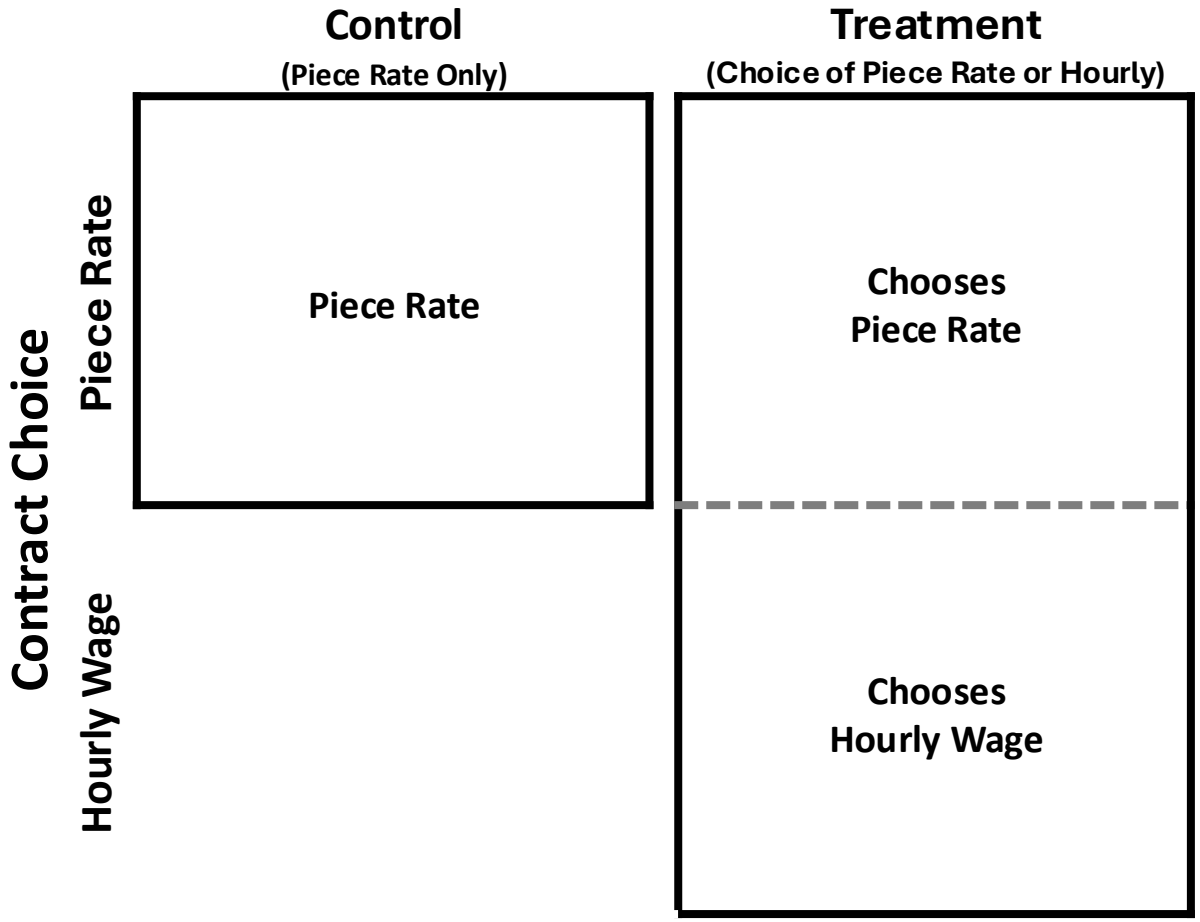

Experimental Design: Single Wage Offer

Simplified Experimental Design

Randomize workers into two offer sets:

- **Treated workers ($W_i = 1$):** offered choice
  - Remain on piece rate ($H_i = 0$)
  - Switch to an hourly wage ($H_i = 1$)
- **Control workers ($W_i = 0$):** no hourly offer
  - Remain on piece rate ($H_i = 0$)

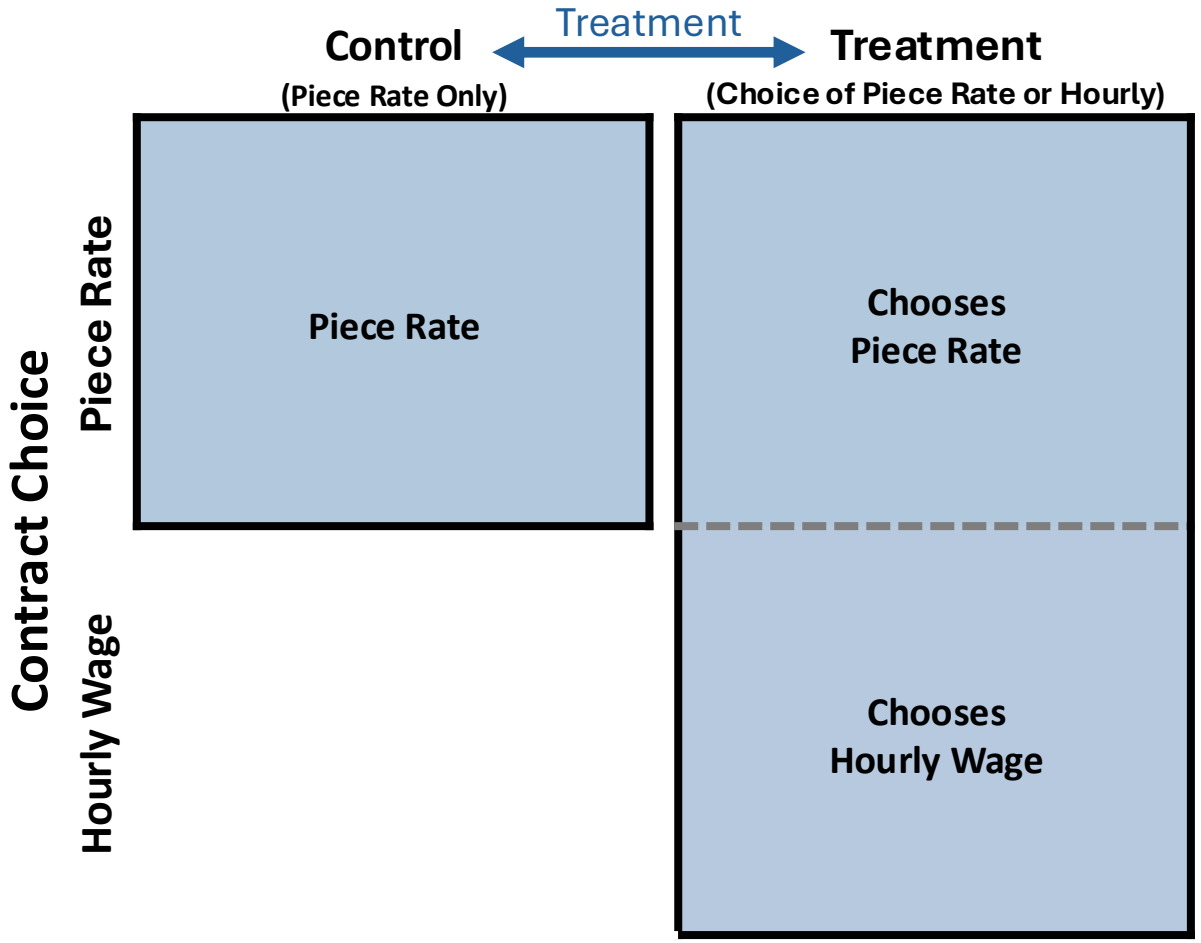

Experimental Design: Single Wage Offer

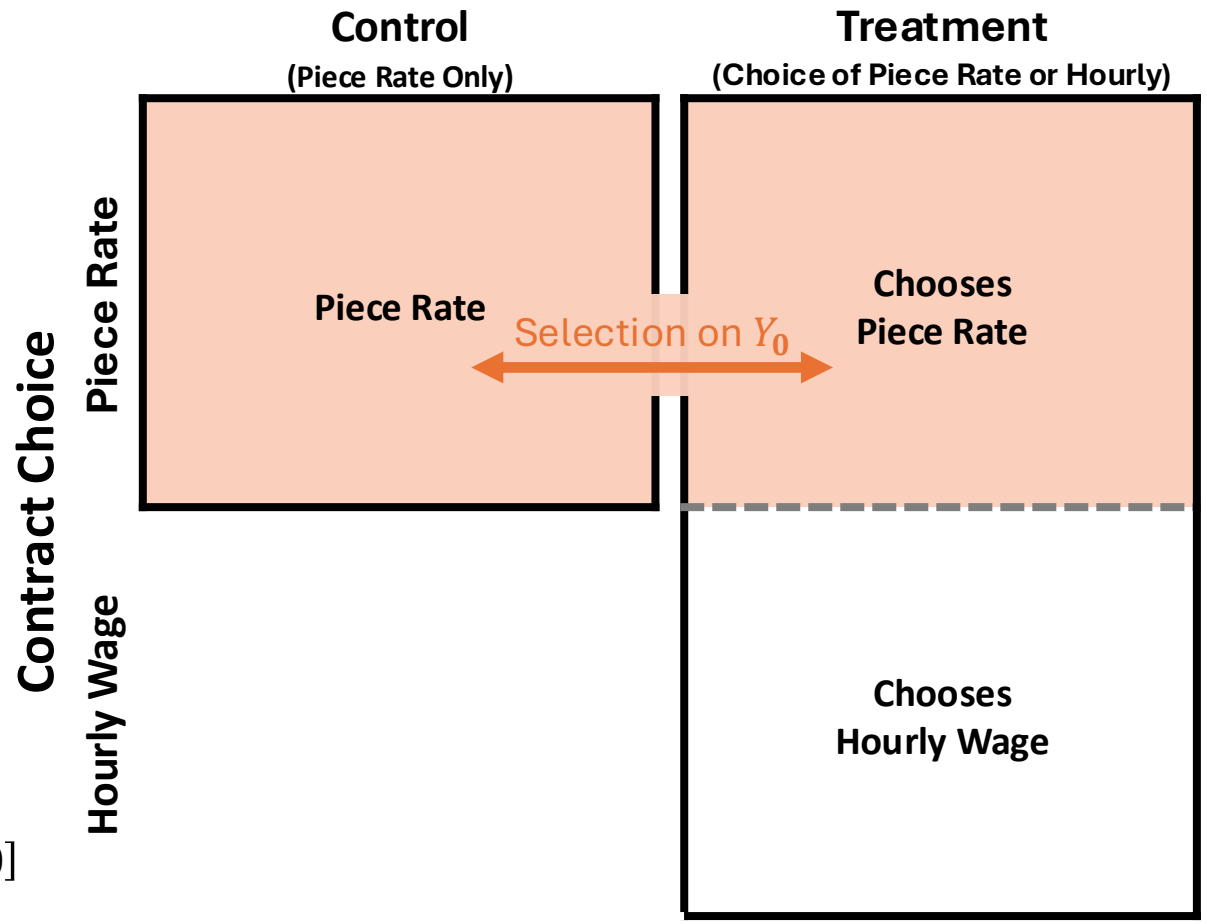

Comparing between workers facing different hourly offers identifies ***treatment effect*** of hourly wages:

$$\frac{E[Y_i|W_i=1]-E[Y_i|W_i=0]}{\Pr(H_i=1|W_i=1)} = \underbrace{E[Y_{1i}-Y_{0i}|H_i=1]}_{\text{Moral Hazard}}$$

Local Average Treatment Effect (LATE)

Experimental Design: Single Wage Offer

Comparing piece-rate workers who faced different offer sets identifies ***selection into treatment:***

$$\frac{E[Y_i|W_i=0]-E[Y_i|H_i=0,W_i=1]}{\Pr(H_i=1|W_i=1)} = \underbrace{E[Y_{0i}|H_i=1]-E[Y_{0i}|H_i=0]}_{\text{Selection on } Y_0}$$

Adverse Selection

Details

Experimental Design: Single Wage Offer

Comparing between workers facing different hourly offers identifies ***treatment effect*** of hourly wages:

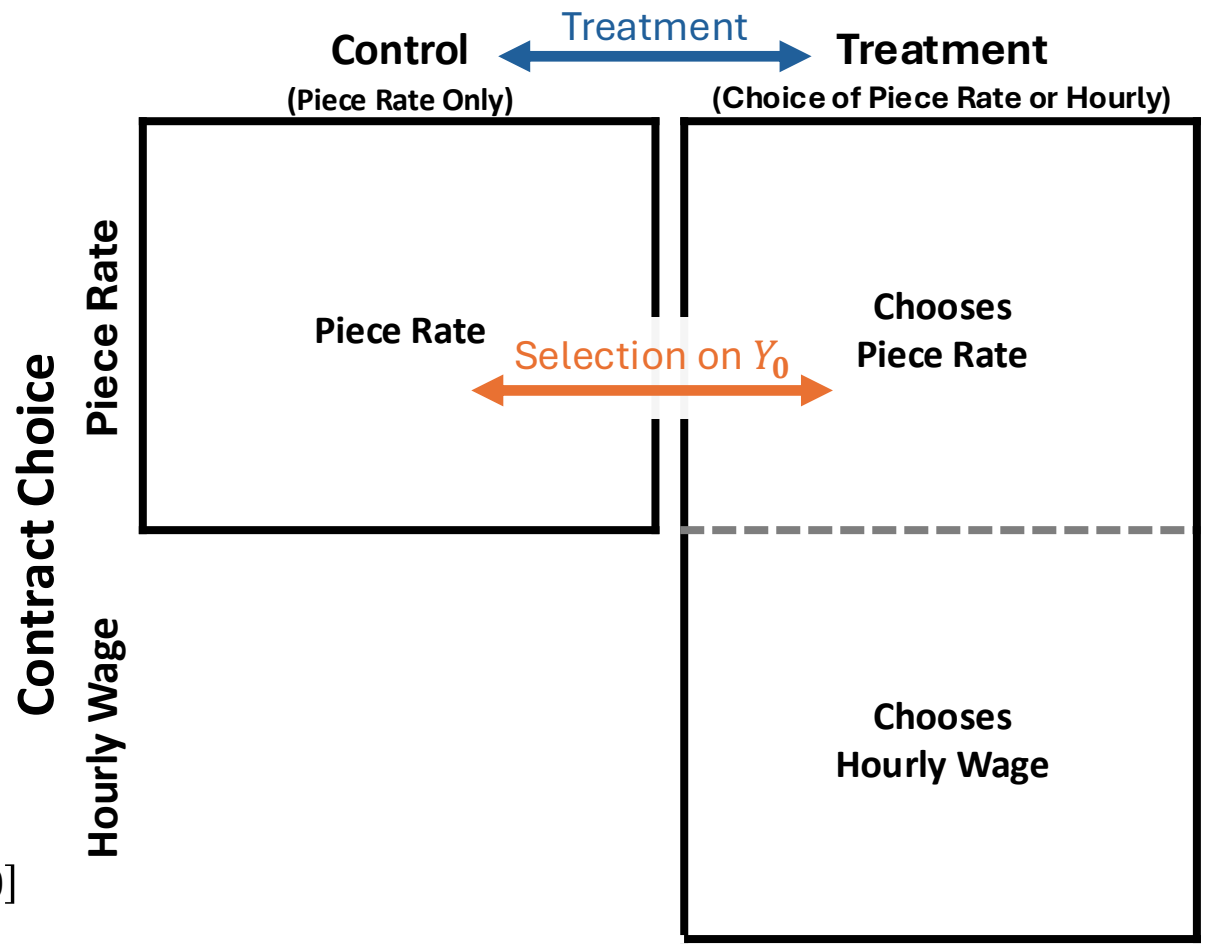

$$\frac{E[Y_i|W_i=1]-E[Y_i|W_i=0]}{\Pr(H_i=1|W_i=1)} = \underbrace{E[Y_{1i}-Y_{0i}|H_i=1]}_{\text{Moral Hazard}}$$

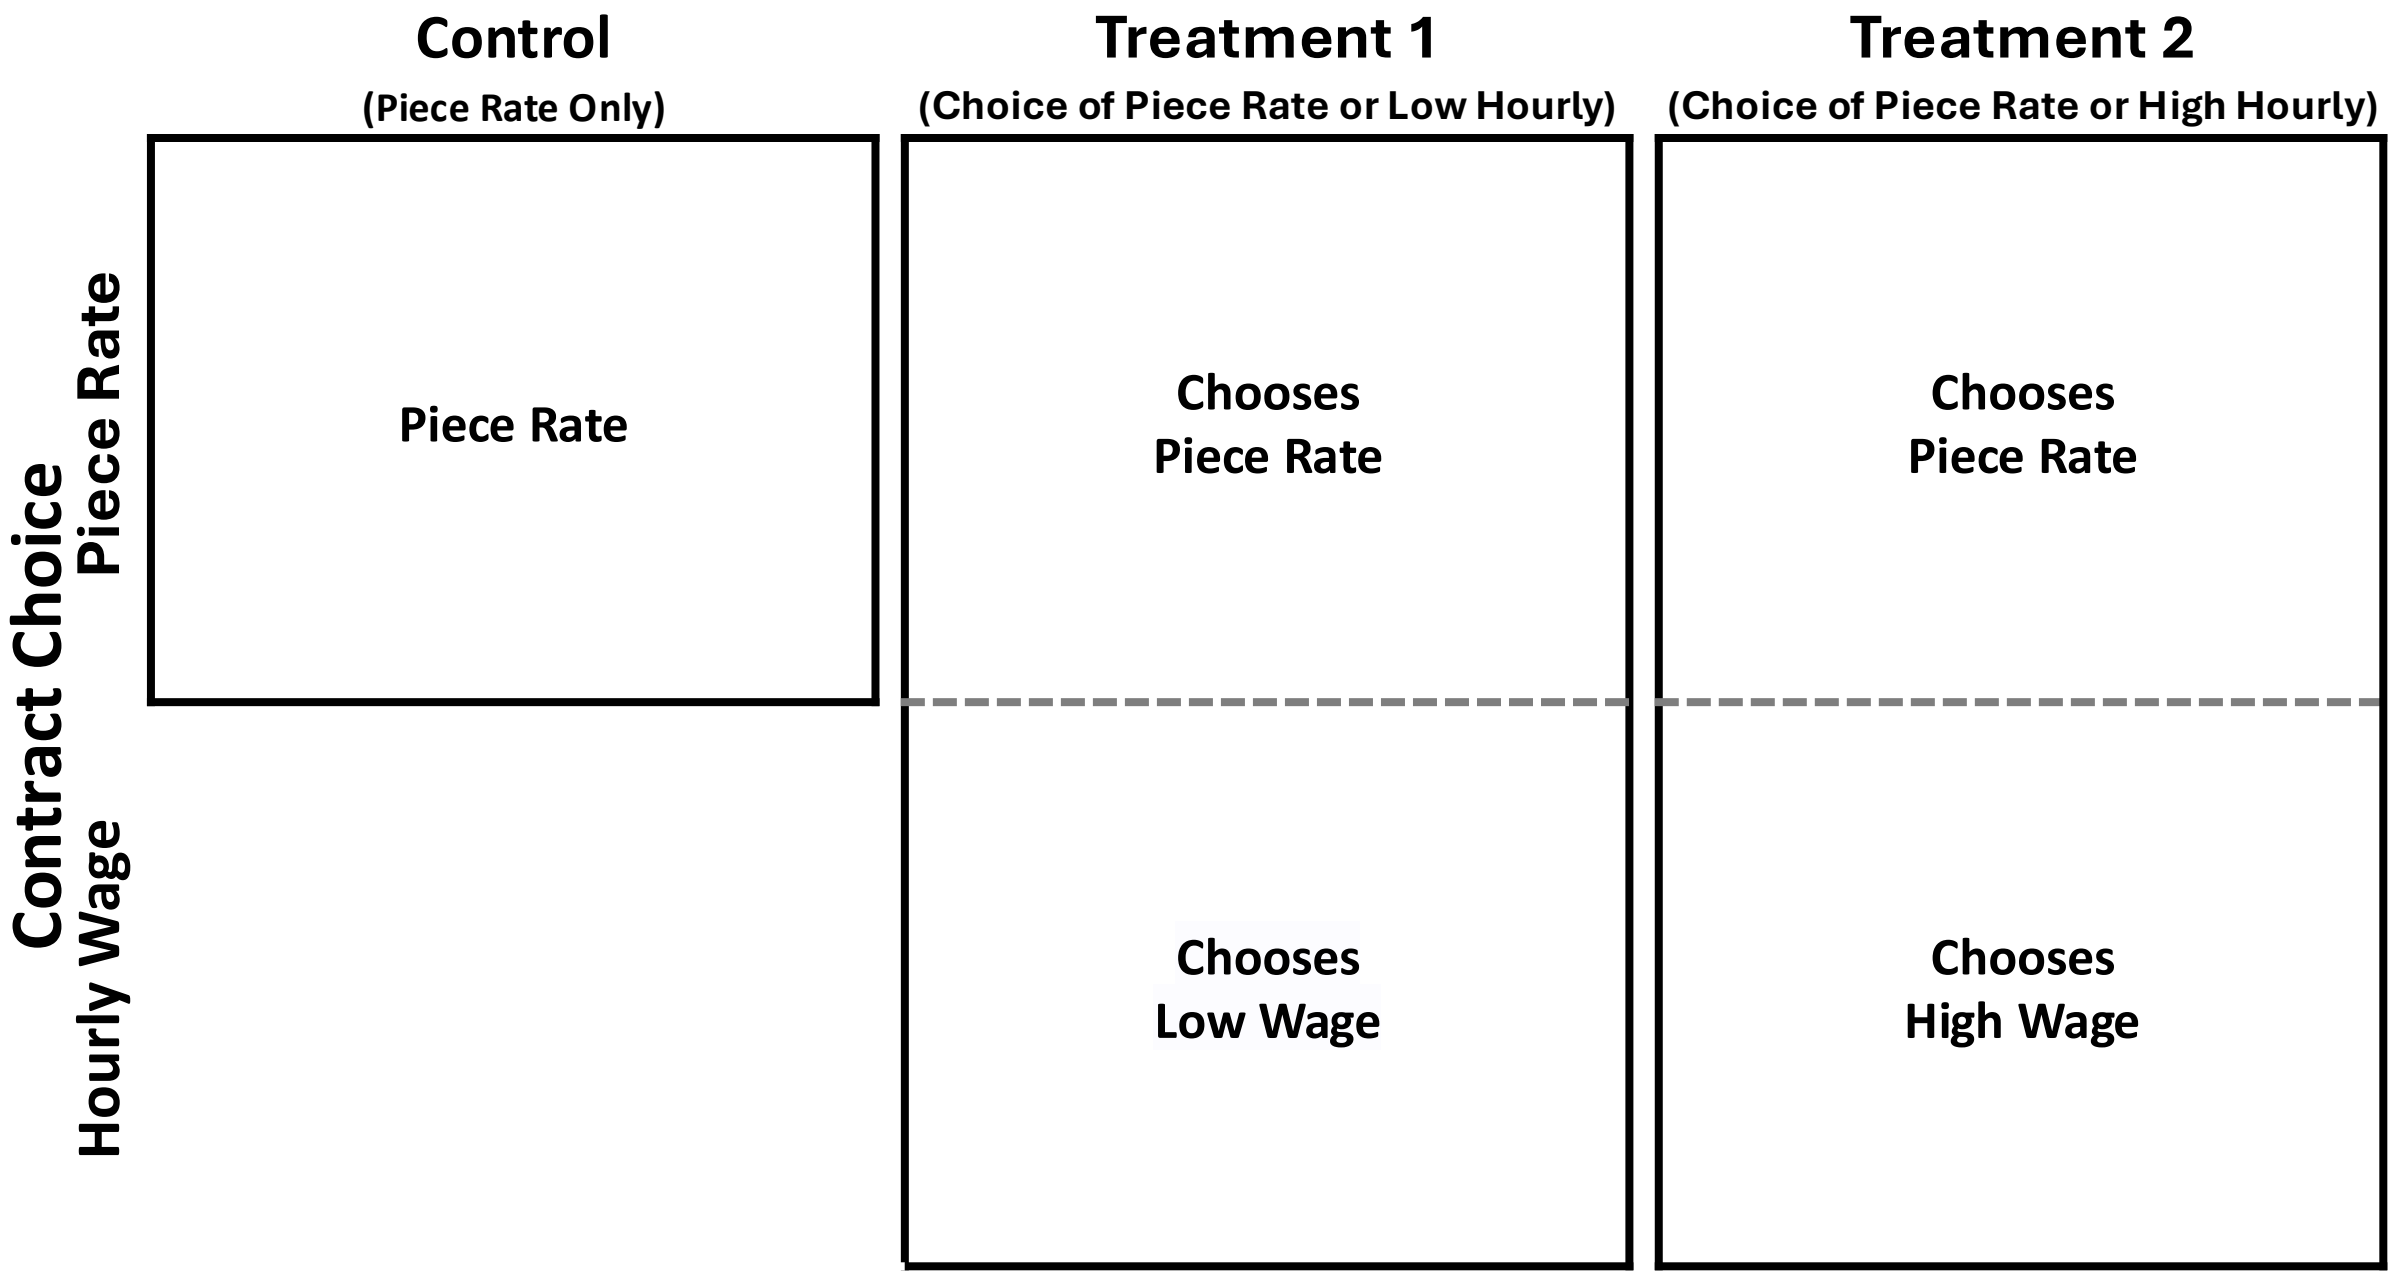

Local Average Treatment Effect (LATE)

Comparing piece-rate workers who faced different offer sets identifies ***selection into treatment:***

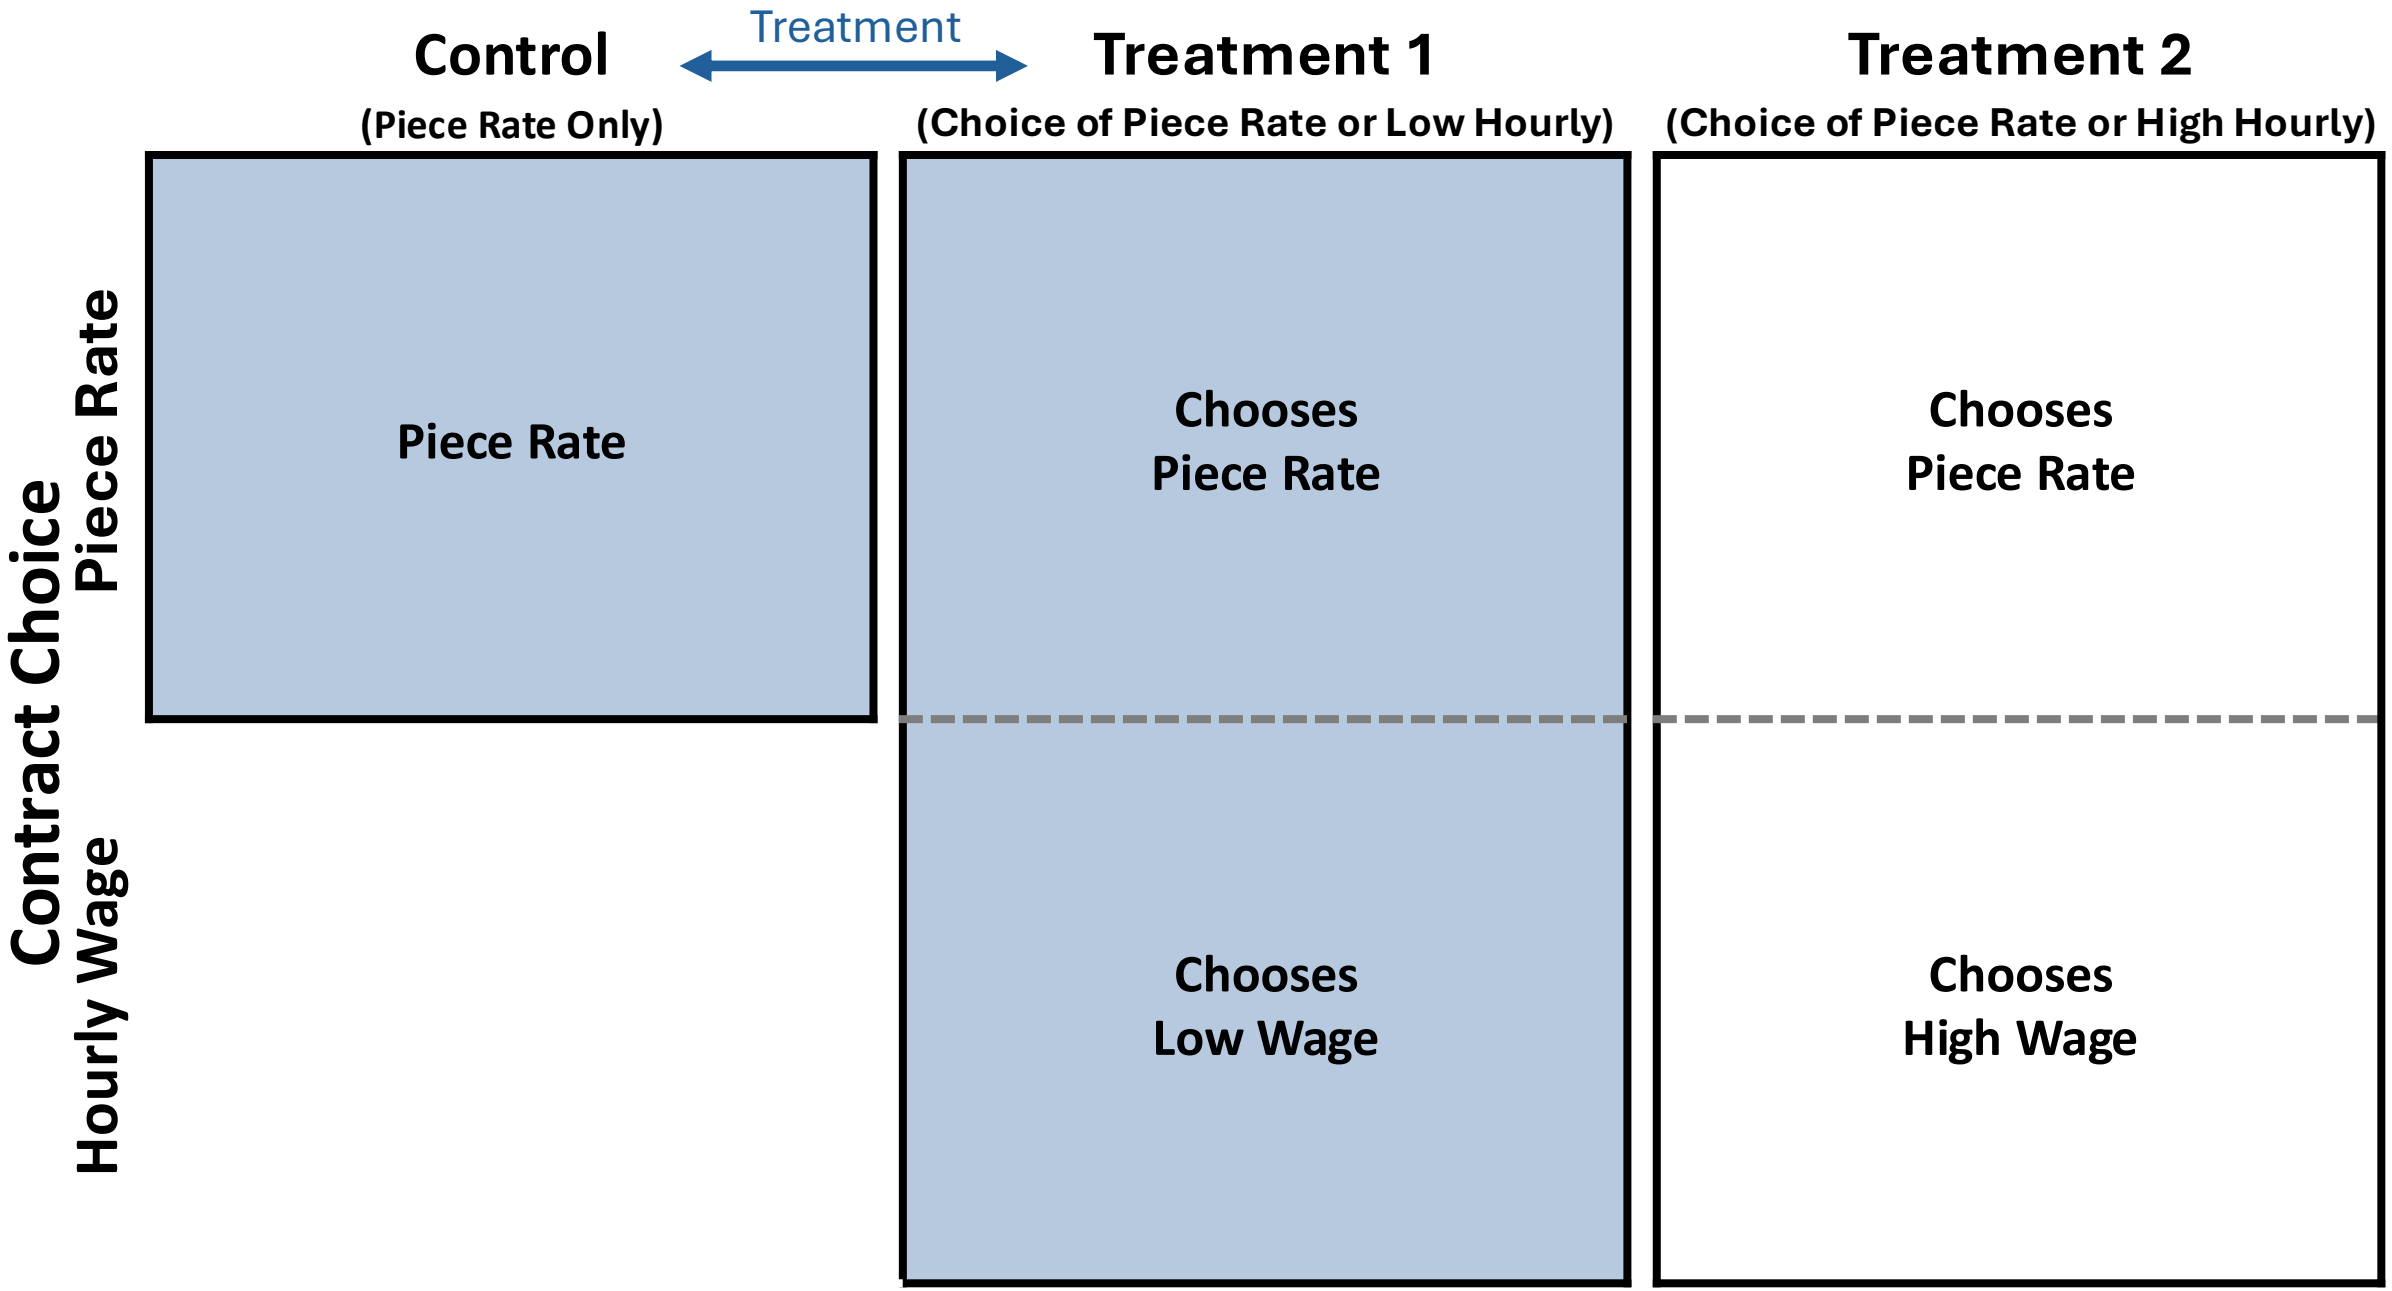

$$\frac{E[Y_i|W_i=0]-E[Y_i|H_i=0,W_i=1]}{\Pr(H_i=1|W_i=1)} = \underbrace{E[Y_{0i}|H_i=1]\ -E[Y_{0i}|H_i=0]}_{\text{Adverse Selection}}$$

$15.00/hr	$0.03 per sentence	100
$18.00/hr	$0.03 per sentence	102
$21.00/hr	$0.03 per sentence	304
	Total:	3030

Balance Test

Experimental Procedure

Workers Recruited

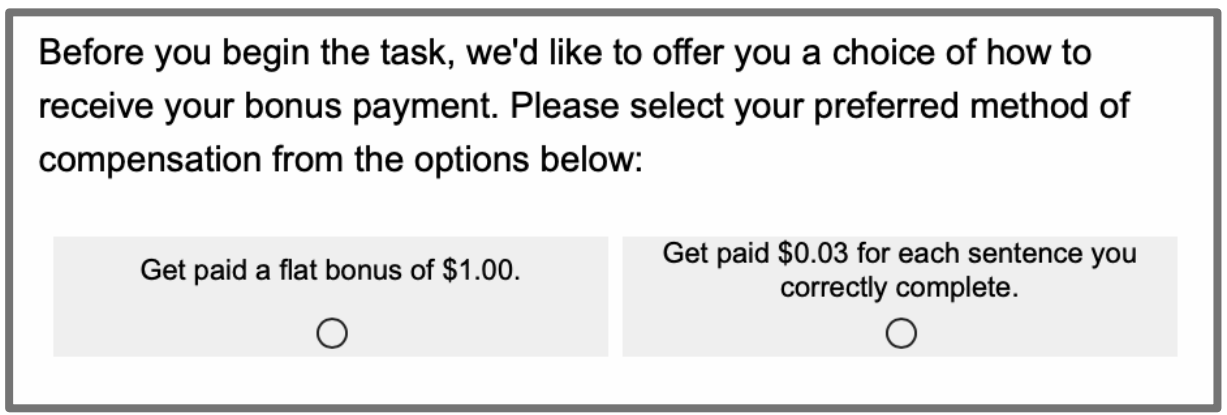

Prolific job posting advertises a $1.00 reward for a five-minute data-entry task, plus $0.03 per correct entry.

Choice of Compensation

Treated workers choose between a $0.03 piece rate and hourly wage offers ranging from $1.20 to $21.00 per hour.

Randomization #1: Wage Offers

Workers are randomly assigned to one of eighteen experimental groups, each with a different menu of bonus wage offers.

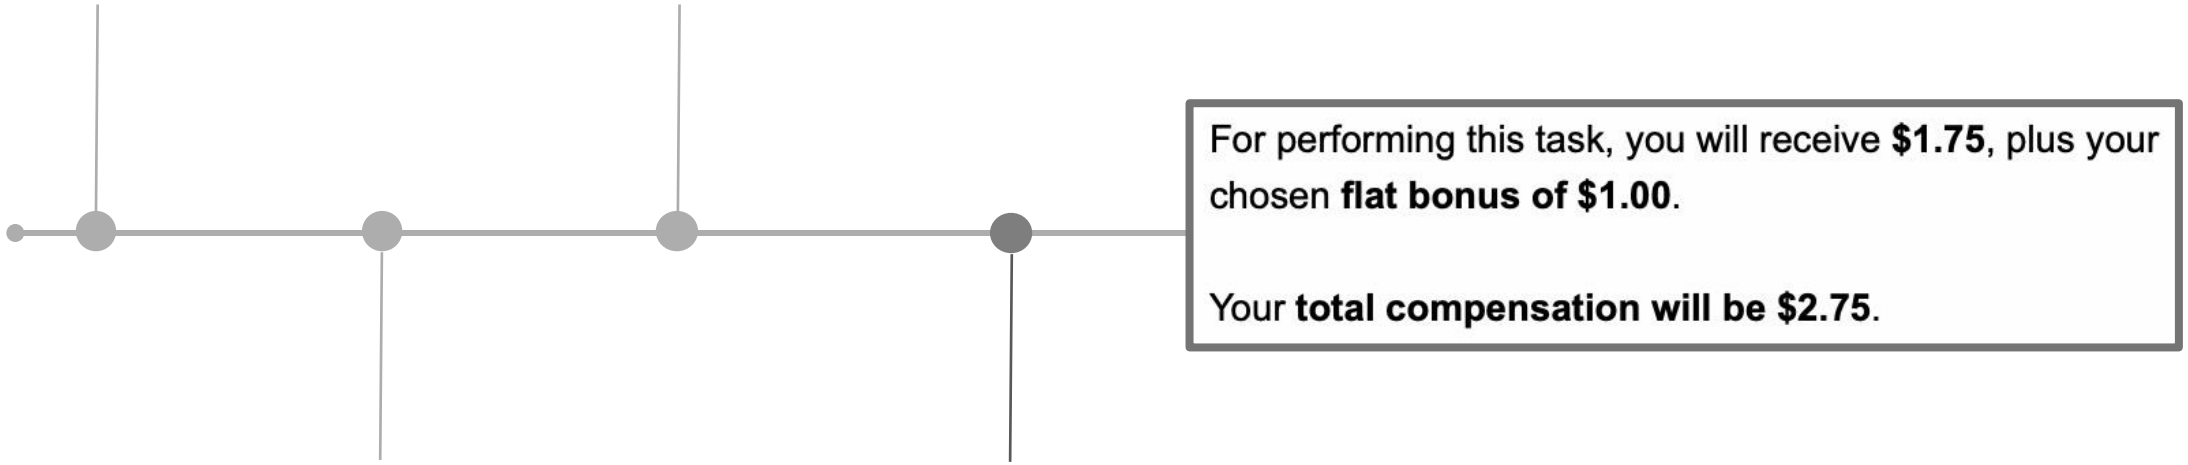

Experimental Procedure

Randomization #1: Wage Offers

Workers are randomly assigned to one of eighteen experimental groups, each with a different menu of bonus wage offers.

Randomization #2: Wage Raises

Before work begins, hourly wages are raised to $21.00 per hour for a random 50 percent of workers who accepted lower-valued hourly offers.

Experimental Procedure

Workers Recruited

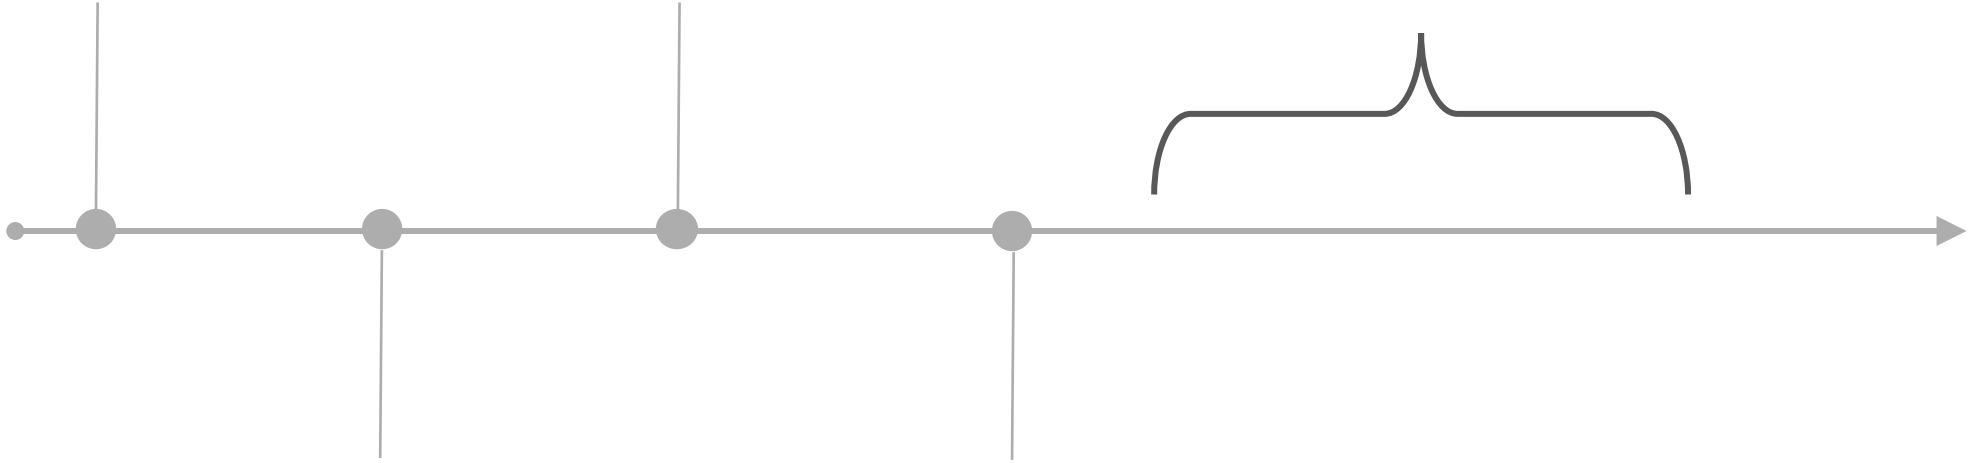

Prolific job posting advertises a $1.00 reward for a five-minute data-entry task, plus $0.03 per correct entry.

Choice of Compensation

Treated workers choose between a $0.03 piece rate and hourly wage offers ranging from $1.20 to $21.00 per hour.

Task Performed

Each worker has five minutes to complete as many data entries as possible. Screen displays worker's progress and remaining time.

Randomization #1: Wage Offers

Workers are randomly assigned to one of eighteen experimental groups, each with a different menu of bonus wage offers.

Randomization #2: Wage Raises

Before work begins, hourly wages are raised to $21.00 per hour for a random 50 percent of workers who accepted lower-valued hourly offers.

You will be shown a series of handwritten sentences. On each page, your task is to type the sentence into the text box below.

Here is one example of a completed sentence:

The quick brown fox jumps over the lazy dog.

Your answers should be as accurate as possible. Please be mindful of capitalization, spacing, and punctuation. When you've completed a sentence, click the "→" button to move on.

You will have 5 minutes to complete as many sentences as you can. You cannot start over, and you can only perform this task once.

Randomization #2: Wage Raises

Before work begins, hourly wages are raised to $21.00 per hour for a random 50 percent of workers who accepted lower-valued hourly offers.

Wages and Bonuses Paid

Within 24 hours of completing the task, workers are paid the $1.00 base reward plus any bonus earnings.

Key Advantages

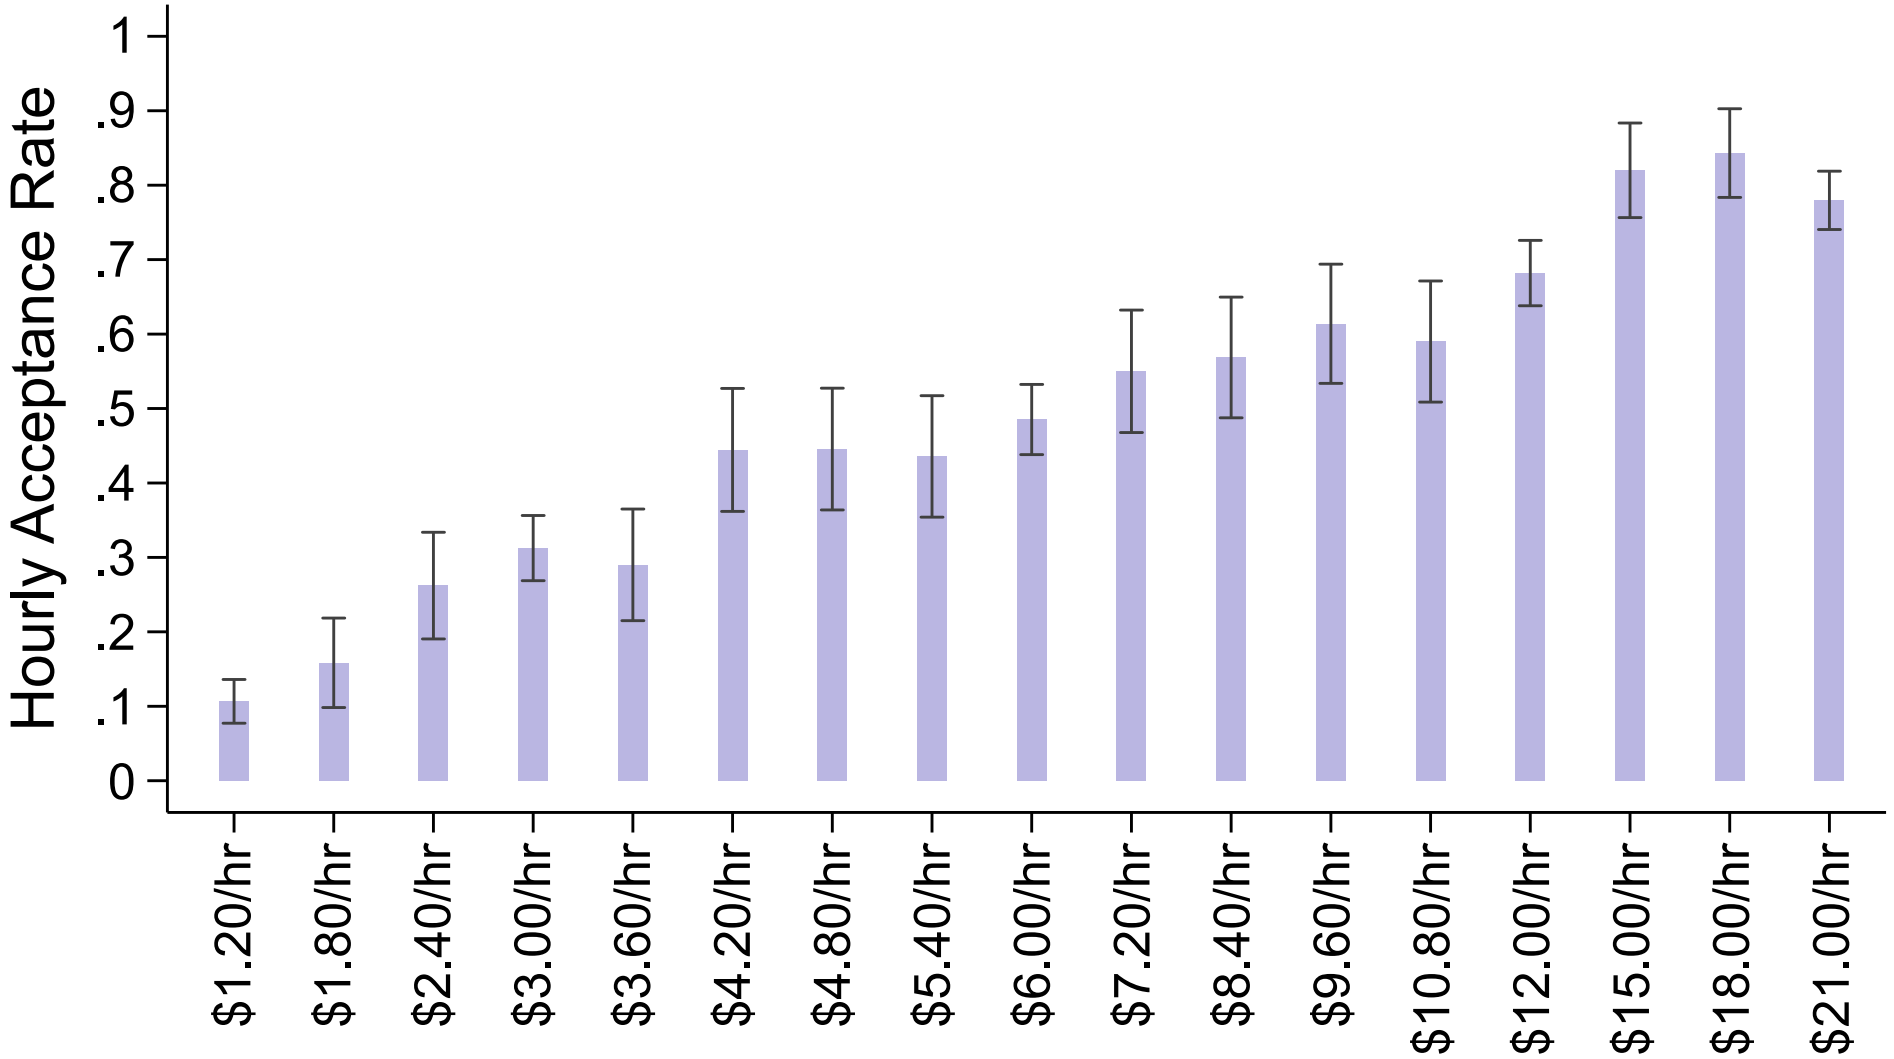

- Sample is not selected into pre-existing employer or contract
  - e.g., sample of firm's existing employees would exclude freelancers
- Control of piece-rate outside option ⇒ *market* supply curve
- Wide range of contract offers, not just those "under the lamppost"
  - i.e., options include potentially *unraveled* contracts that are not profitable
- Observe output for all workers—both *accepters* and *decliners*

  ⇒ Can estimate selection on Y_0 and Y_1
- Experimental task is designed to be as generalizable as possible
  - 66% of US workers type on the job
  - Workers don't know it's an experiment
  - Task features tend to *attenuate* welfare effects relative to other gig markets
- Highly Replicable!

$$Y_i = \alpha H_i + \beta_0(1 - H_i) \times W_i + \beta_1 H_i \times W_i + \gamma H_i \times W_i^P + \boldsymbol{\xi} \boldsymbol{X_i} + \epsilon_i$$

Marginal Selection Raw Output Value

Selection by Log Wage Offer

$$Y_i = \sum_{w \in \mathbb{W}} [(\beta_0^w (1 - H_i) + \beta_1^w H_i) \times \mathbf{1}\{W_i = w\}] + \gamma H_i \times W_i^P + \boldsymbol{\xi} \boldsymbol{X_i} + \epsilon_i$$

Raw Output Value

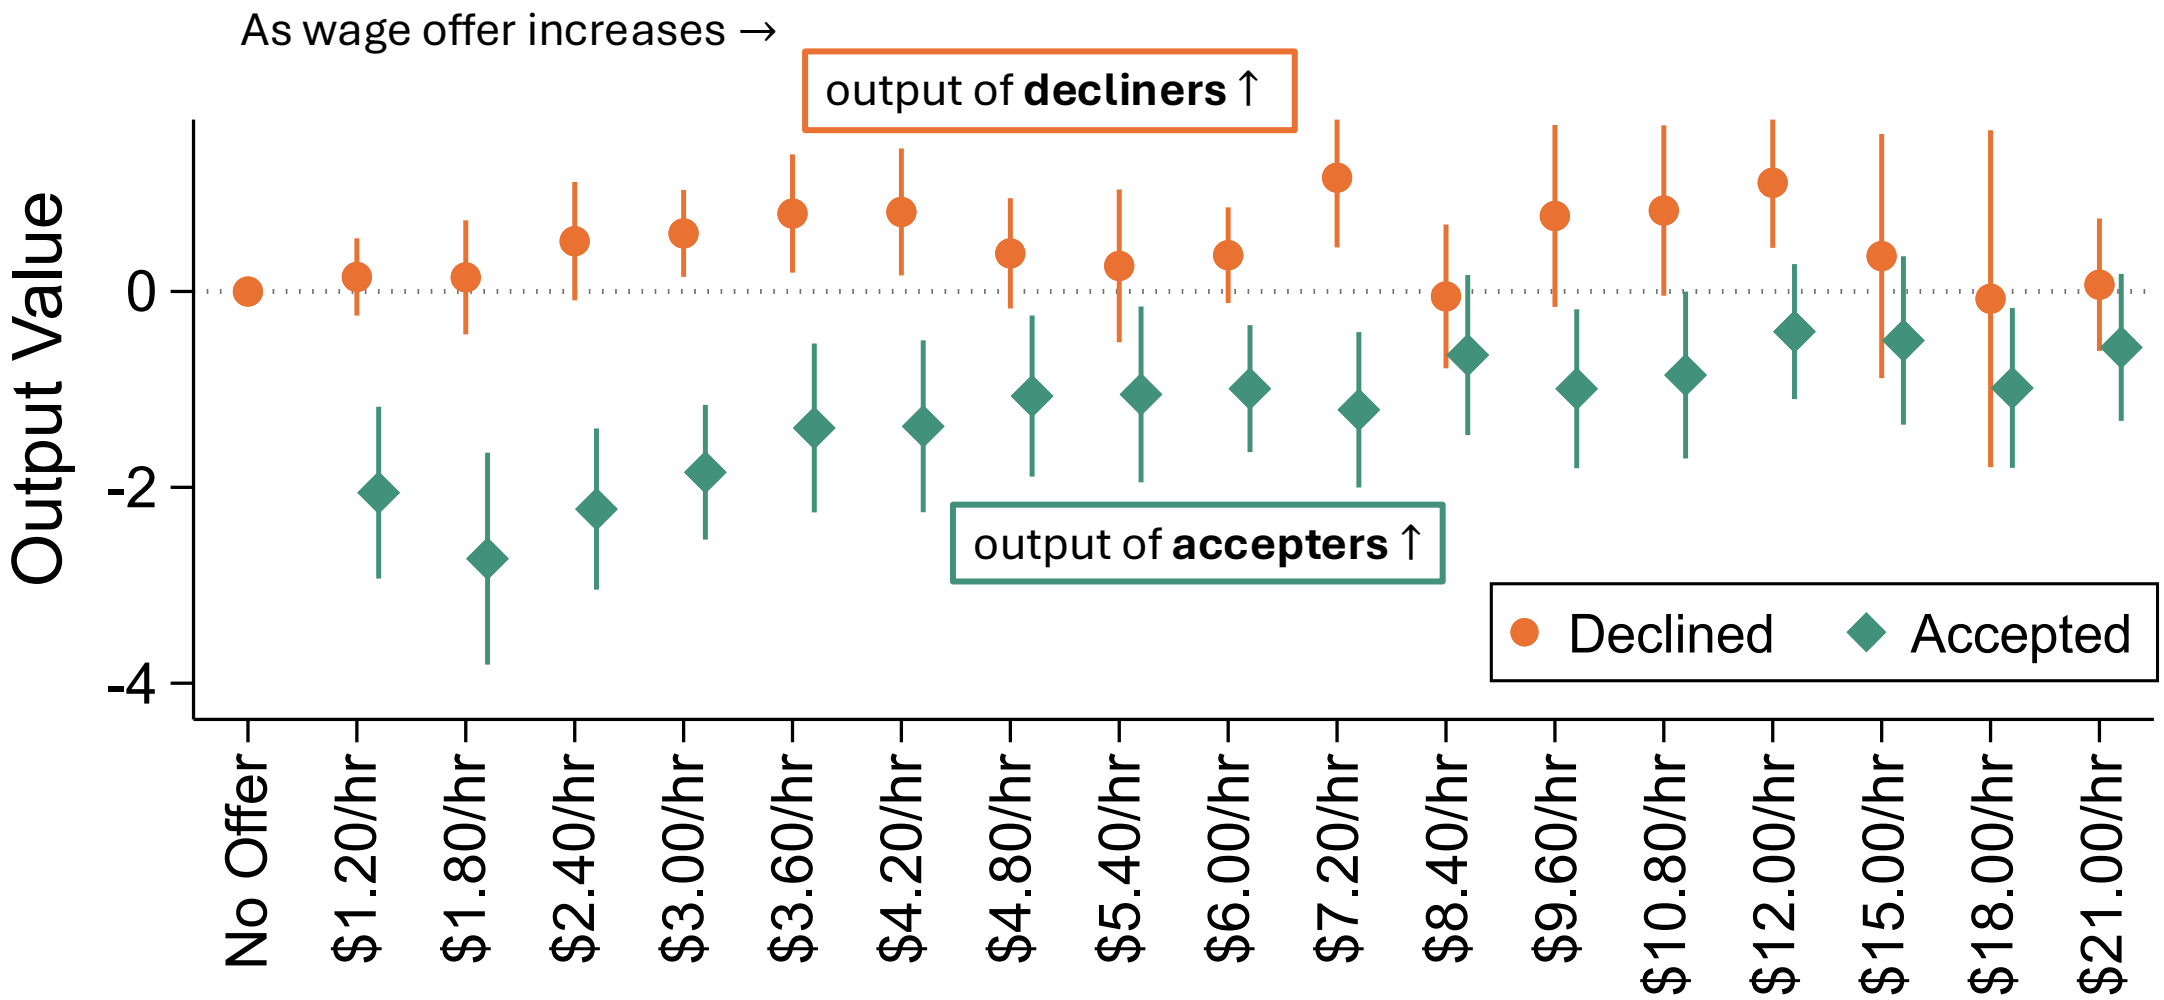

Selection by Log Wage Offer

$$Y_i = \sum_{w \in \mathbb{W}} [(\beta_0^w (1 - H_i) + \beta_1^w H_i) \times \mathbf{1}\{W_i = w\}] + \gamma H_i \times W_i^P + \boldsymbol{\xi} \boldsymbol{X_i} + \epsilon_i$$

Raw Output Value

Selection by Log Wage Offer

$$Y_i = \sum_{w \in \mathbb{W}} [(\beta_0^w (1 - H_i) + \beta_1^w H_i) \times \mathbf{1}\{W_i = w\}] + \gamma H_i \times W_i^P + \boldsymbol{\xi} \boldsymbol{X_i} + \epsilon_i$$

Raw Output Value

Summary so far…

Let $\overline{w}_i \equiv$ **hourly reservation wage** (the lowest hourly wage i would accept)
Estimates of *average* treatment and selection into fixed wage, $w \Rightarrow$

Evidence of Moral Hazard

Hourly wages reduce average output among workers who accept.

$$E[Y_{1i} - Y_{0i} | \overline{w}_i \leq w] < 0$$

Treatment Effect

Evidence of Adverse Selection

Low-productivity workers are more likely to accept low hourly wage offers.

$$\frac{\partial}{\partial w} E[Y_{0i} | \overline{w}_i > w] > 0$$

Selection on Y_0

$$\frac{\partial}{\partial w} E[Y_{1i} | \overline{w}_i \leq w] > 0$$

Selection on Y_1

What are the implications for… Market equilibrium? Social welfare? Public policy?

Summary so far…

Let $\overline{w}_i \equiv$ **hourly reservation wage** (the lowest hourly wage i would accept)
Estimates of *average* treatment and selection into fixed wage, $w \Rightarrow$

Evidence of Moral Hazard

Hourly wages reduce average output among workers who accept.

$$E[Y_{1i} - Y_{0i} | \overline{w}_i \leq w] < 0$$

Treatment Effect

Evidence of Adverse Selection

Low-productivity workers are more likely to accept low hourly wage offers.

$$\frac{\partial}{\partial w} E[Y_{0i} | \overline{w}_i > w] > 0$$

Selection on Y_0

$$\frac{\partial}{\partial w} E[Y_{1i} | \overline{w}_i \leq w] > 0$$

Selection on Y_1

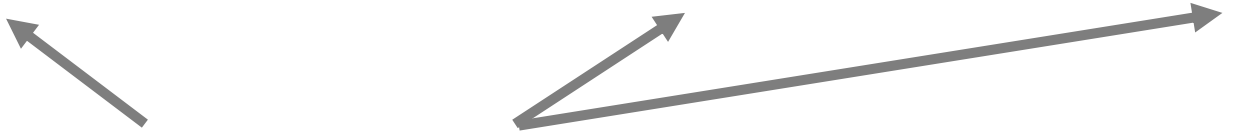

What are the implications for… Market equilibrium? Social welfare? Public policy?

Model shows how answers depend on the *marginal* worker ($\overline{w}_i = w$)

$$E[Y_{1i} - Y_{0i} | \overline{w}_i = w]$$

$$E[Y_{0i} | \overline{w}_i = w]$$

$$E[Y_{1i} | \overline{w}_i = w]$$

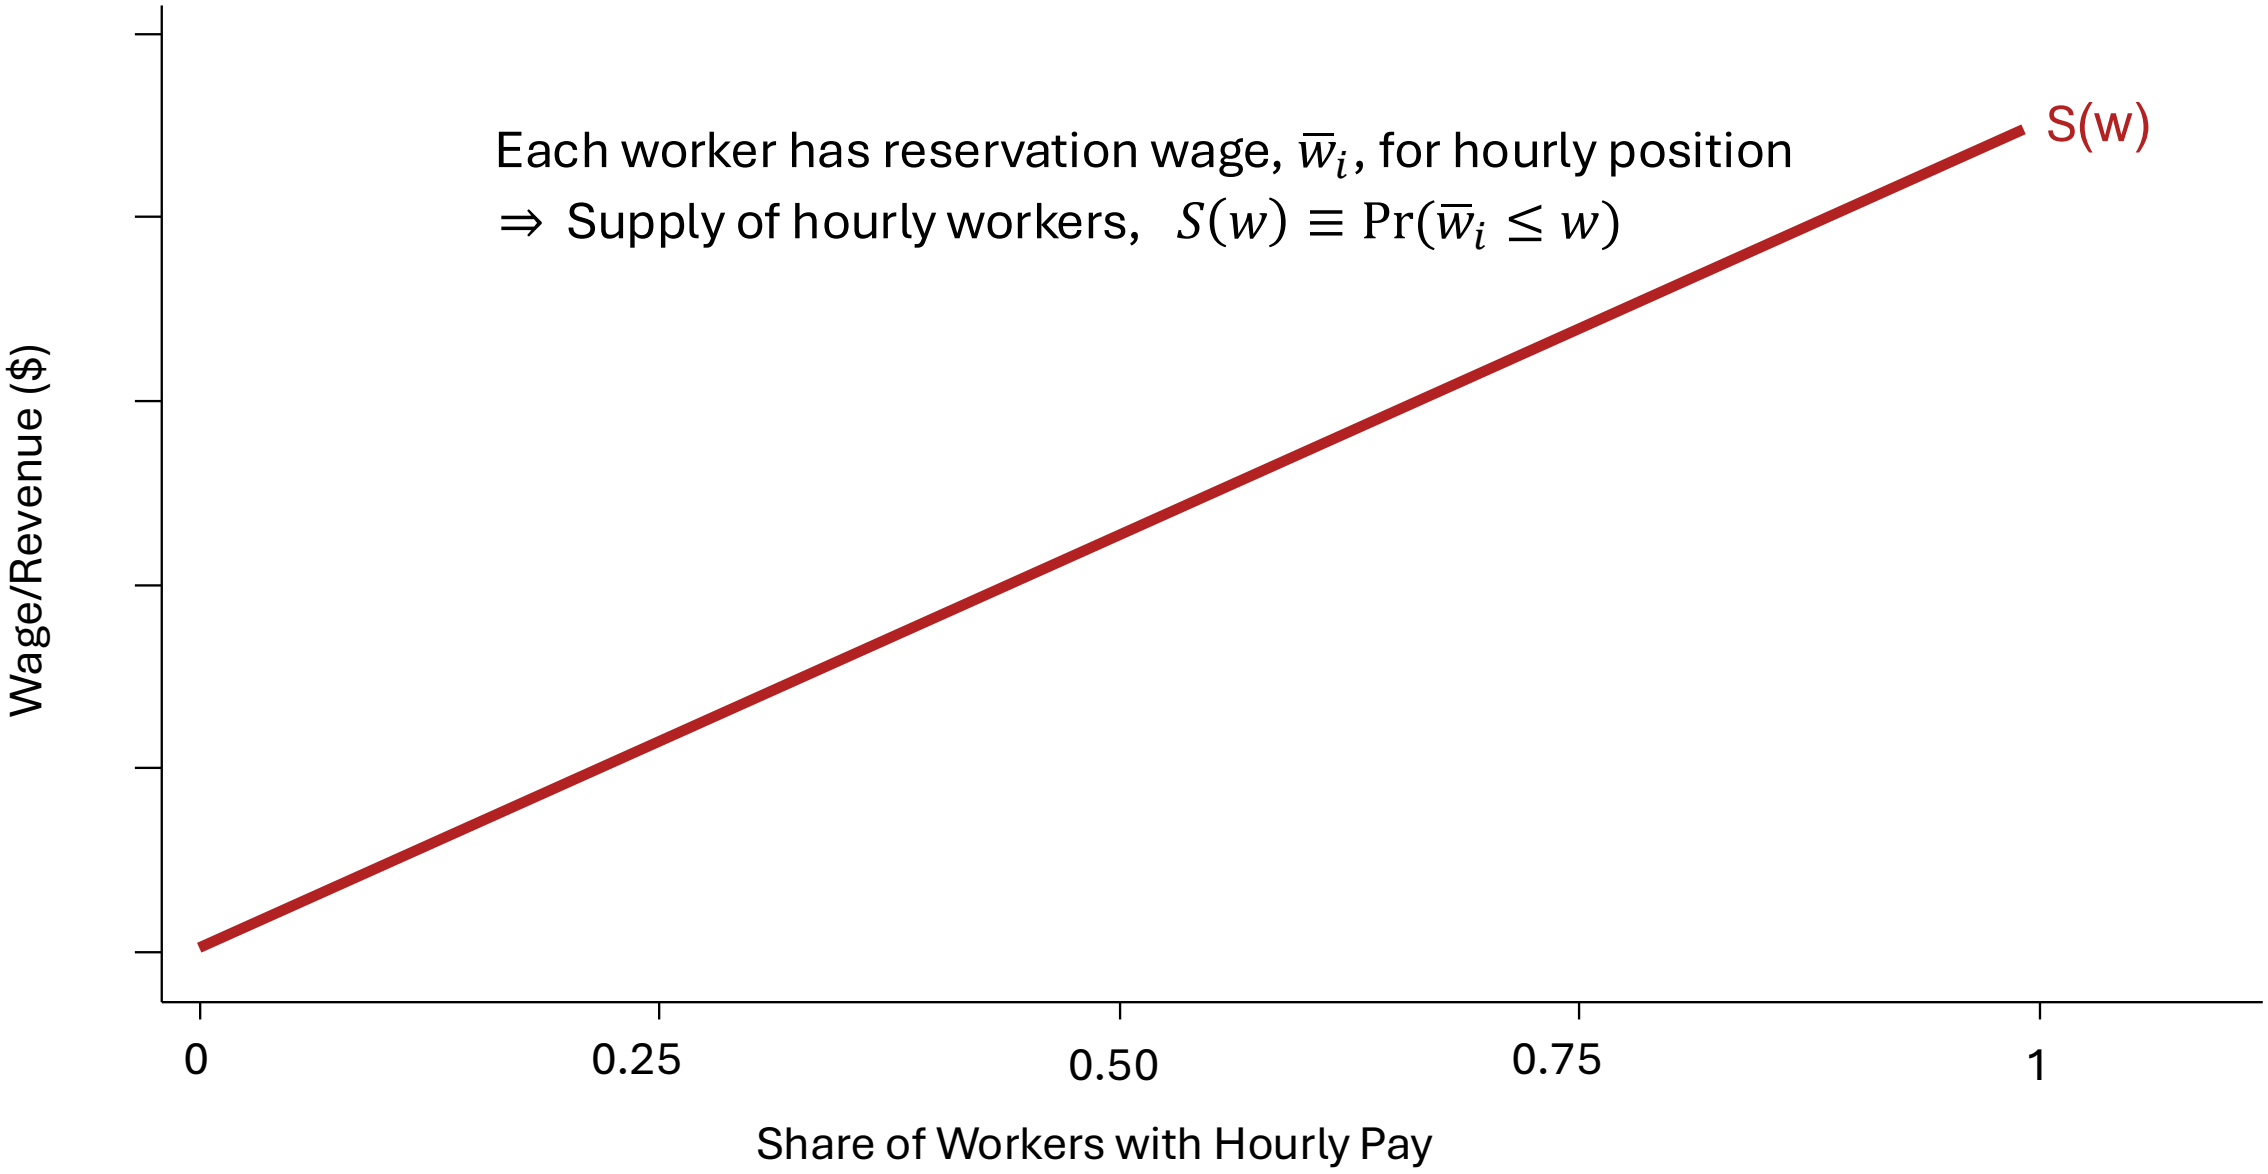

Identified with Marginal Treatment Effects (MTE)

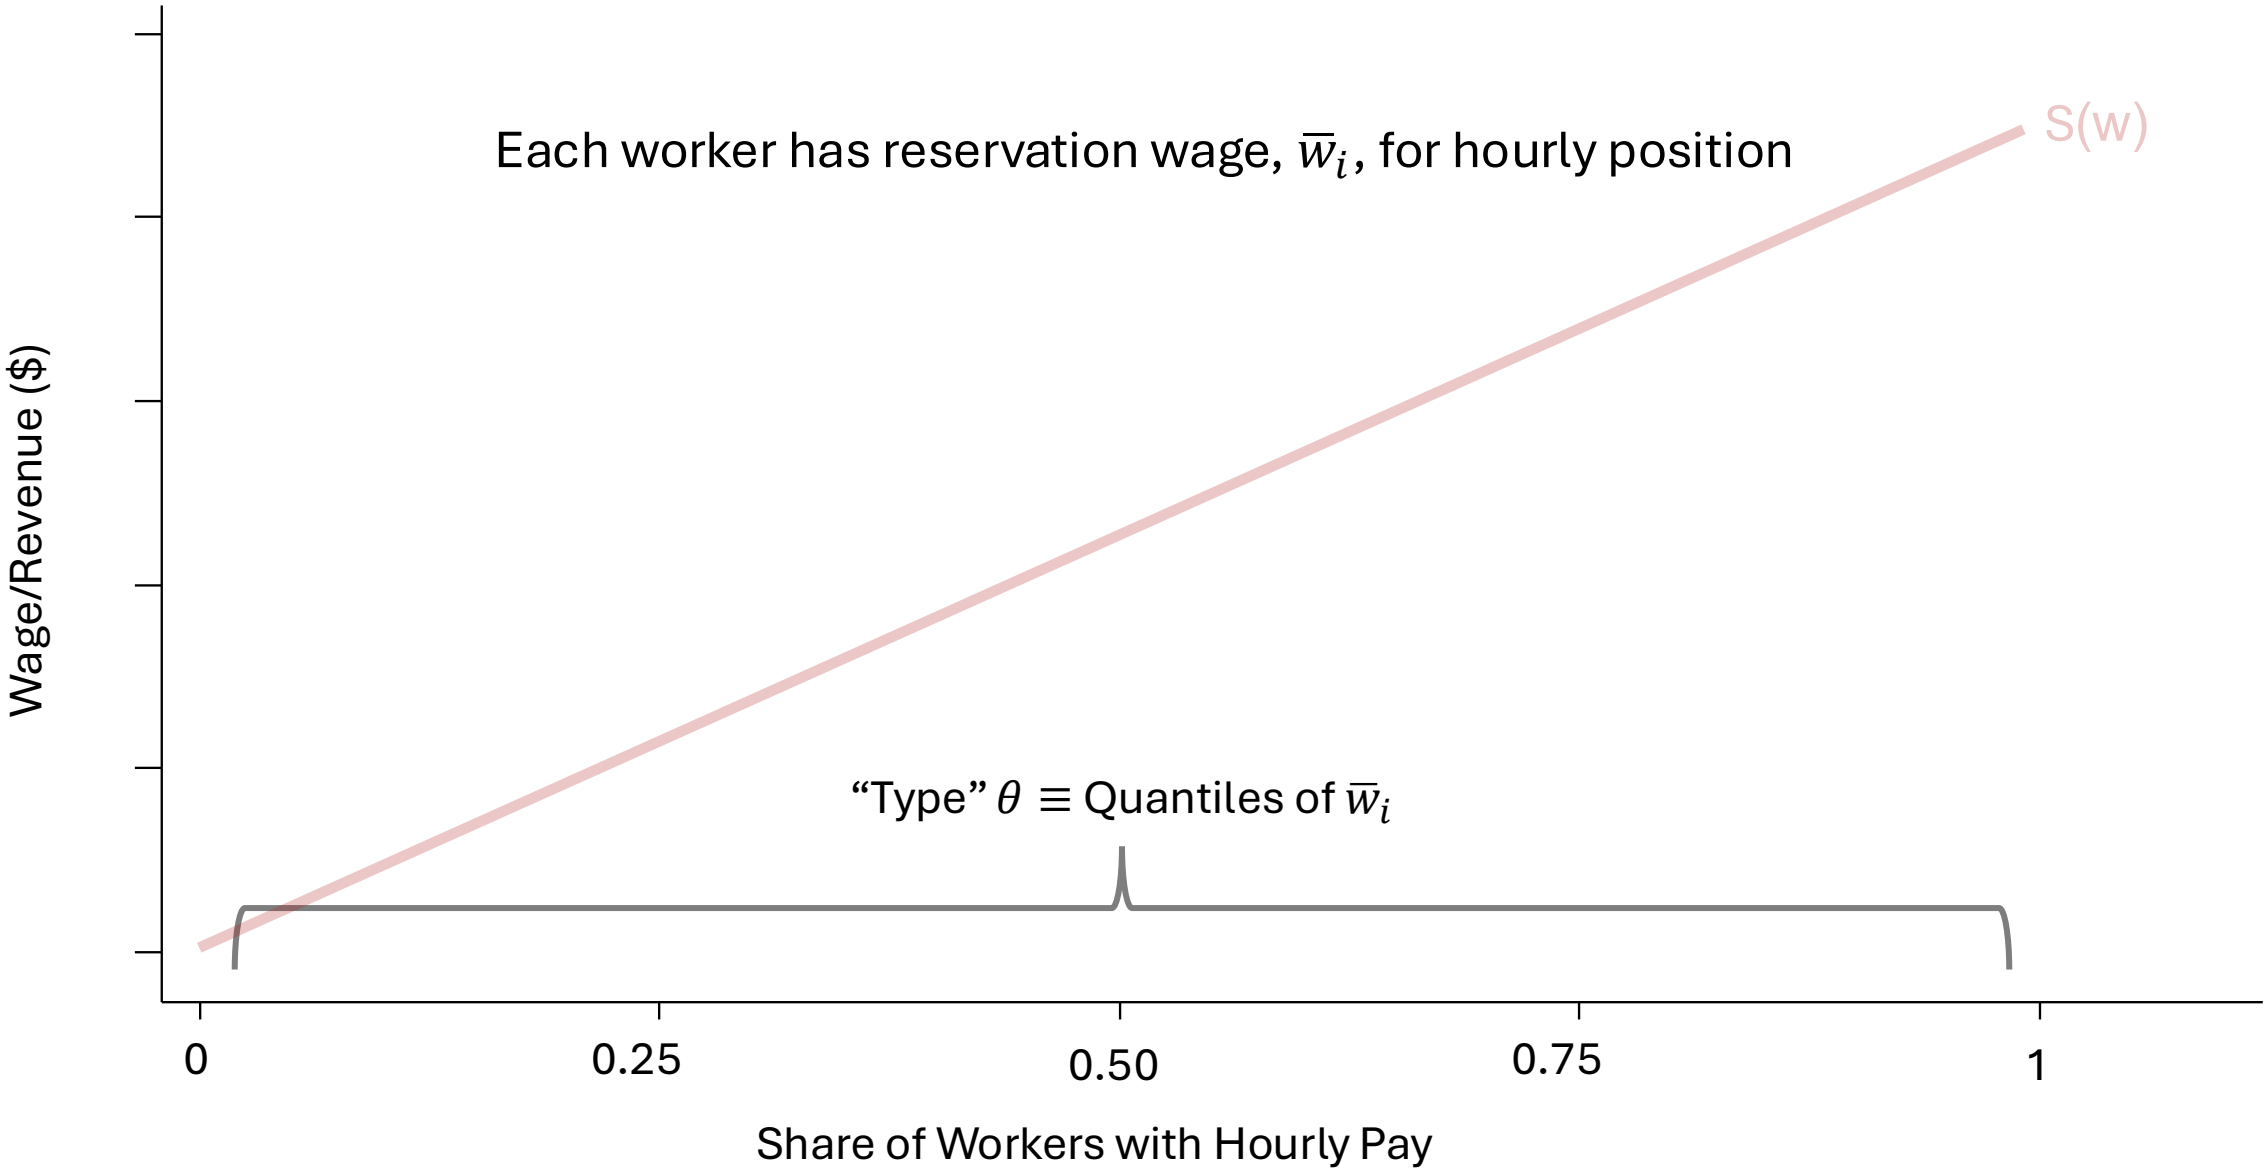

Outline

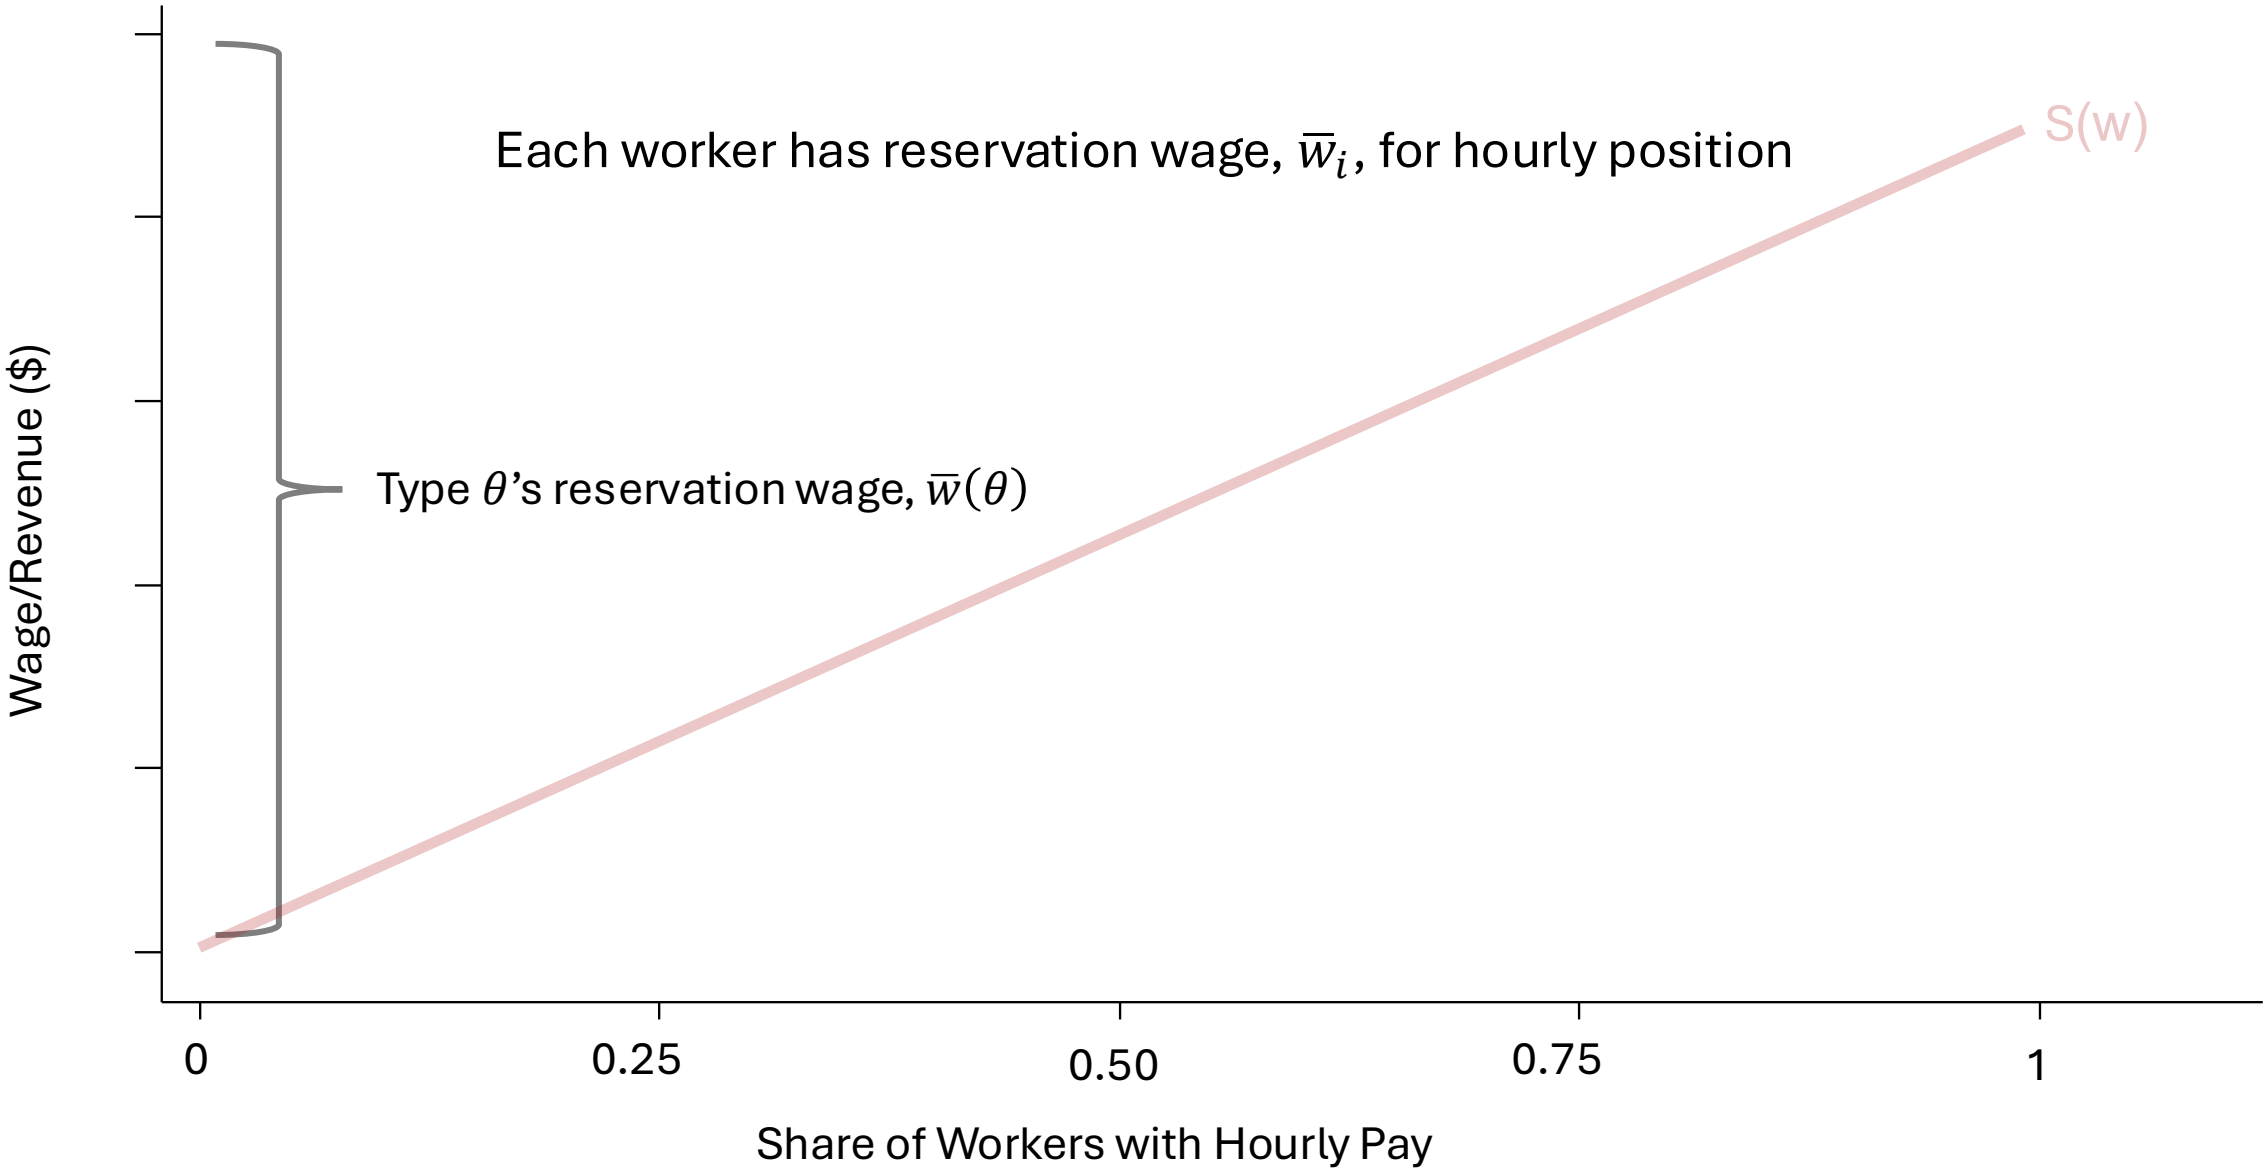

1. Experimental Design and Results
2. Model of Asymmetric Information
3. Estimates of Marginal Value and Welfare Loss
4. Optimal Fixed-Wage Subsidy and Piece-Rate Tax
5. Extensions

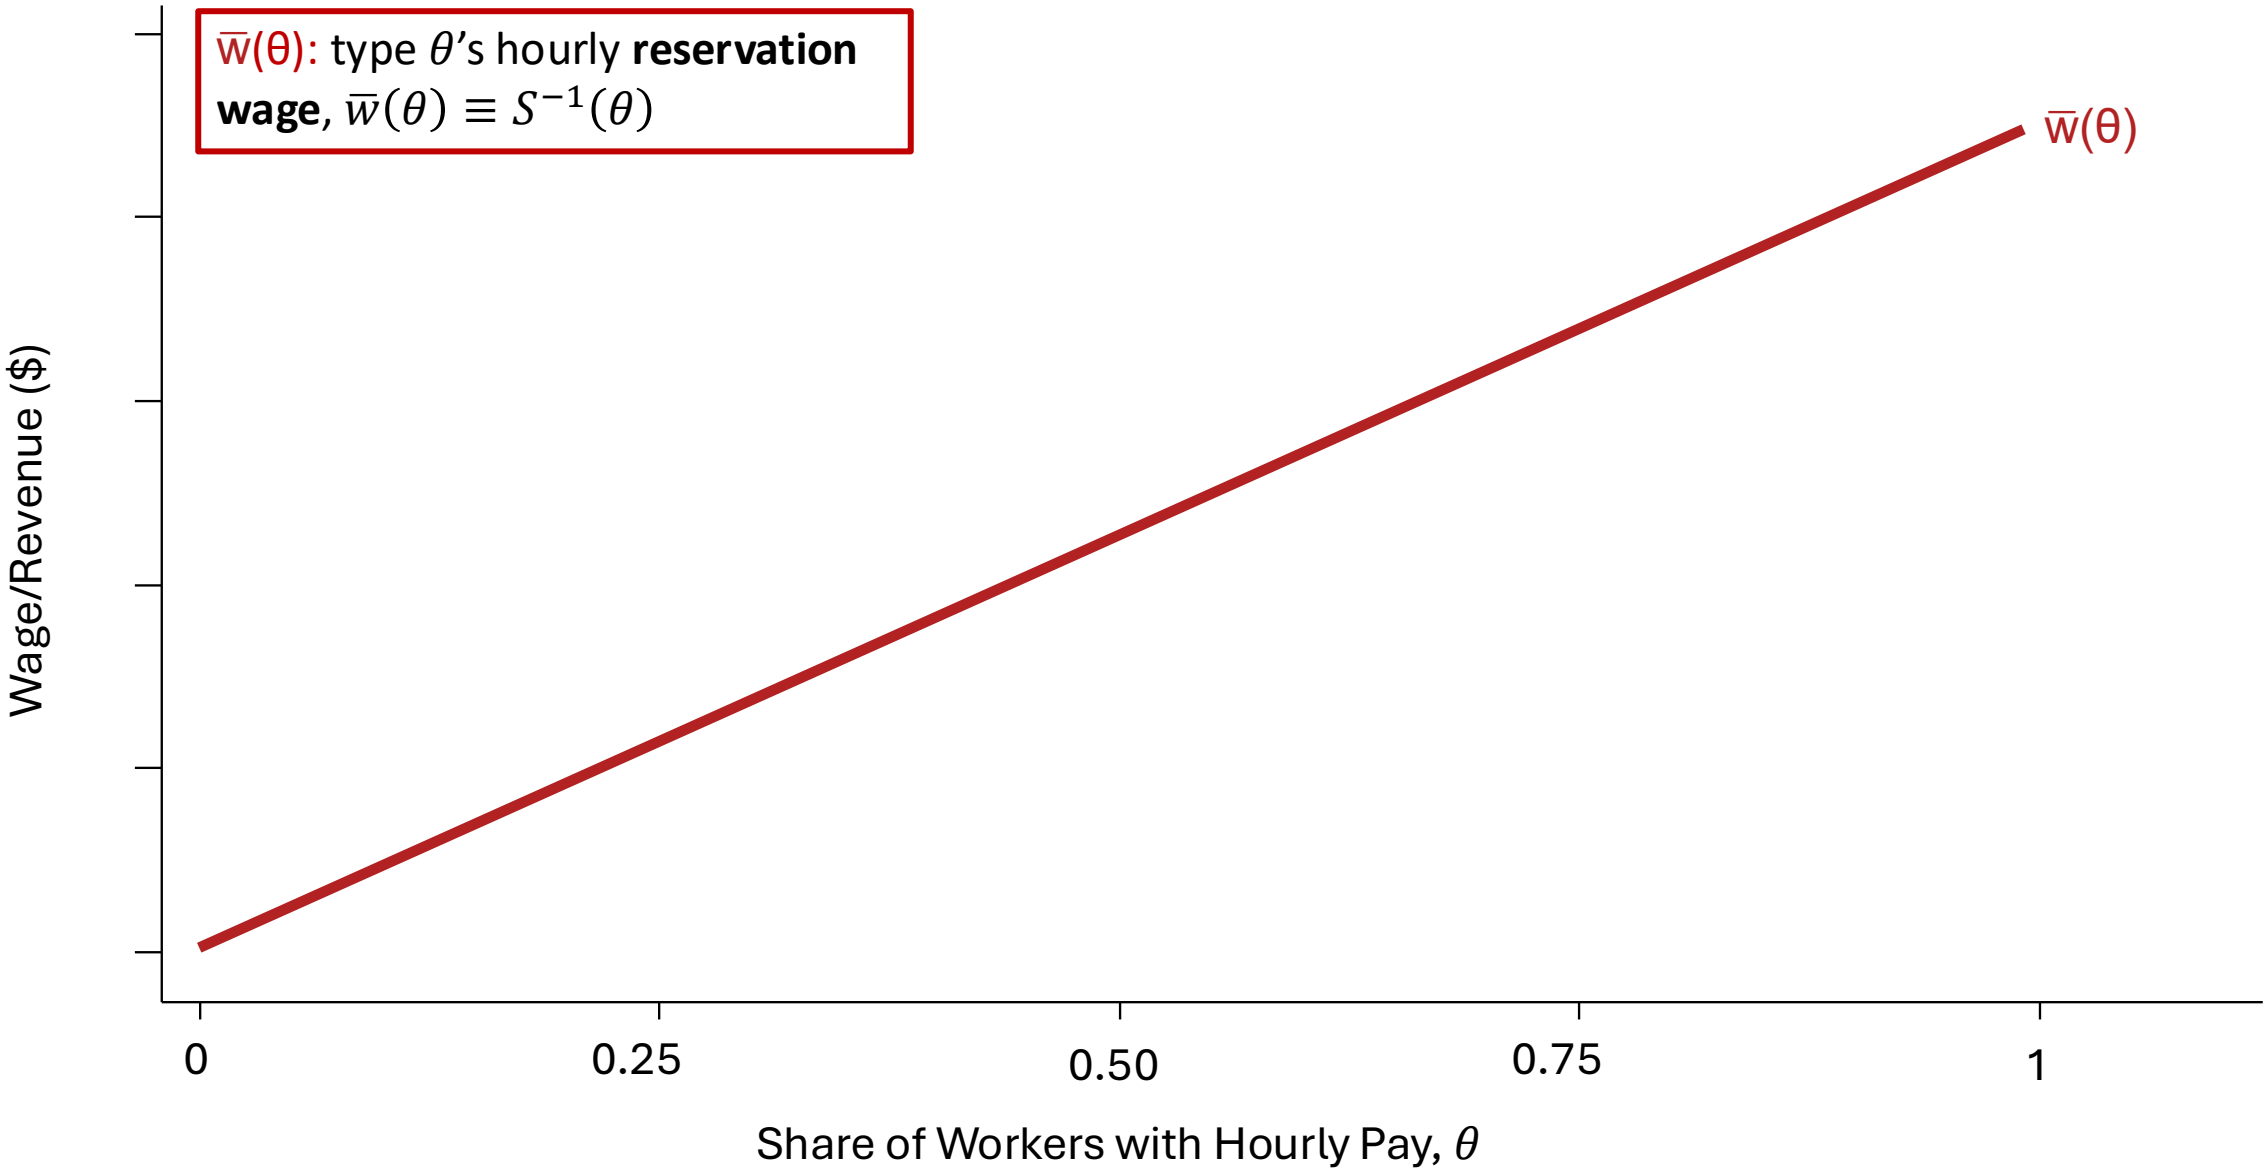

Model

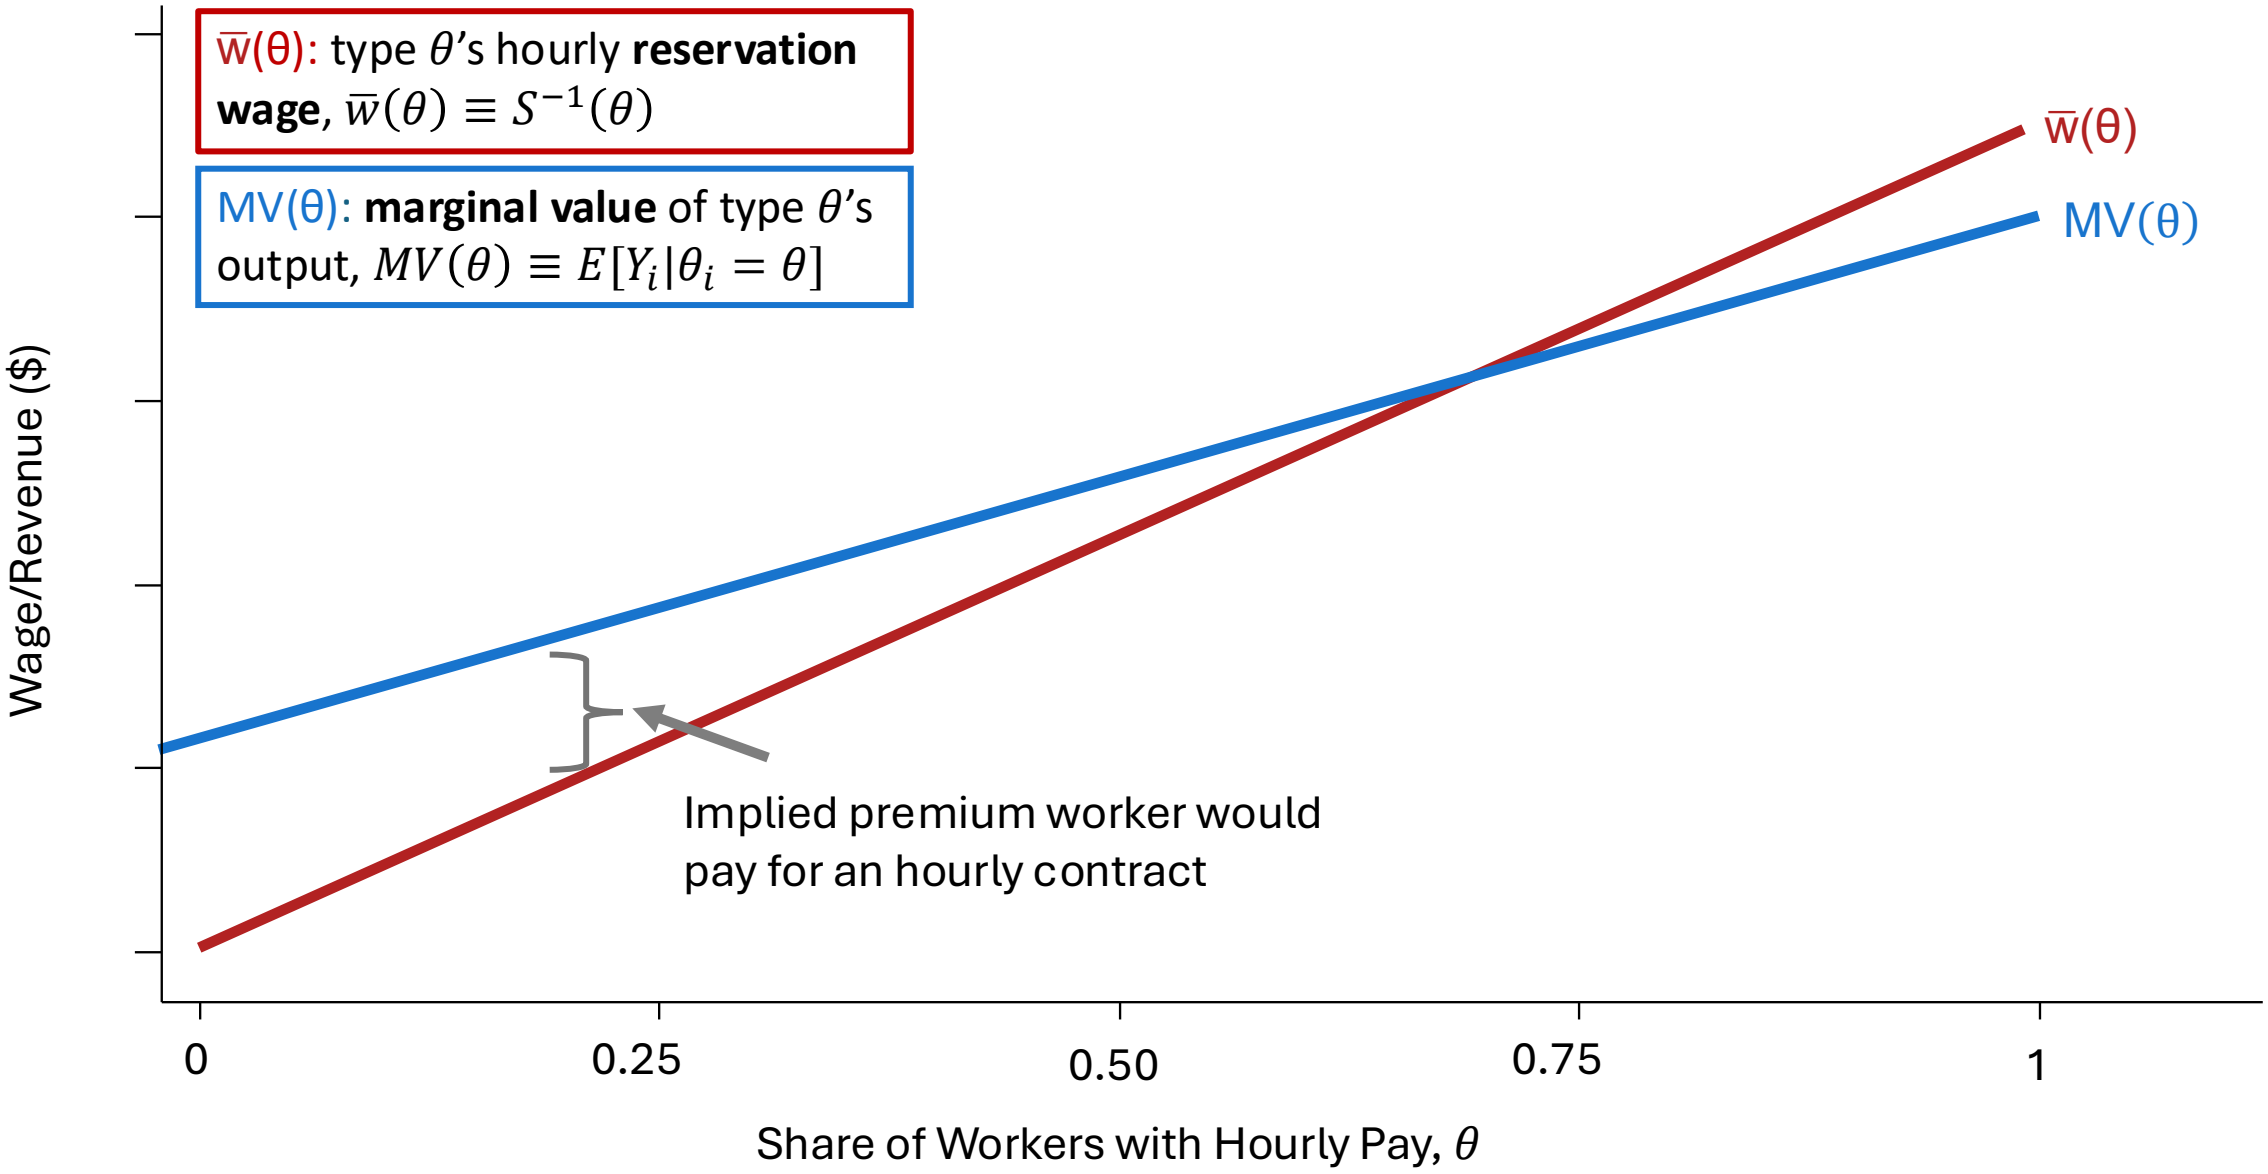

- Population of observationally equivalent (pre-screened) workers
- Each worker produces hourly output $q_i = f(\zeta_i, e_i, \nu_i)$
  - ζ_i: (unobserved) worker characteristics
  - e_i: individual effort, potentially influenced by the contract (moral hazard)
  - ν_i: random noise
- Value of worker i's output is $Y_i \equiv pq_i$, where $p \equiv$ price per unit q
- Firms have two options:
  1. Buy output at per-unit market price p (e.g., piece rate, freelance hire)
  2. Offer worker *ex-ante* hourly wage, w, in exchange for claim on realized q_i

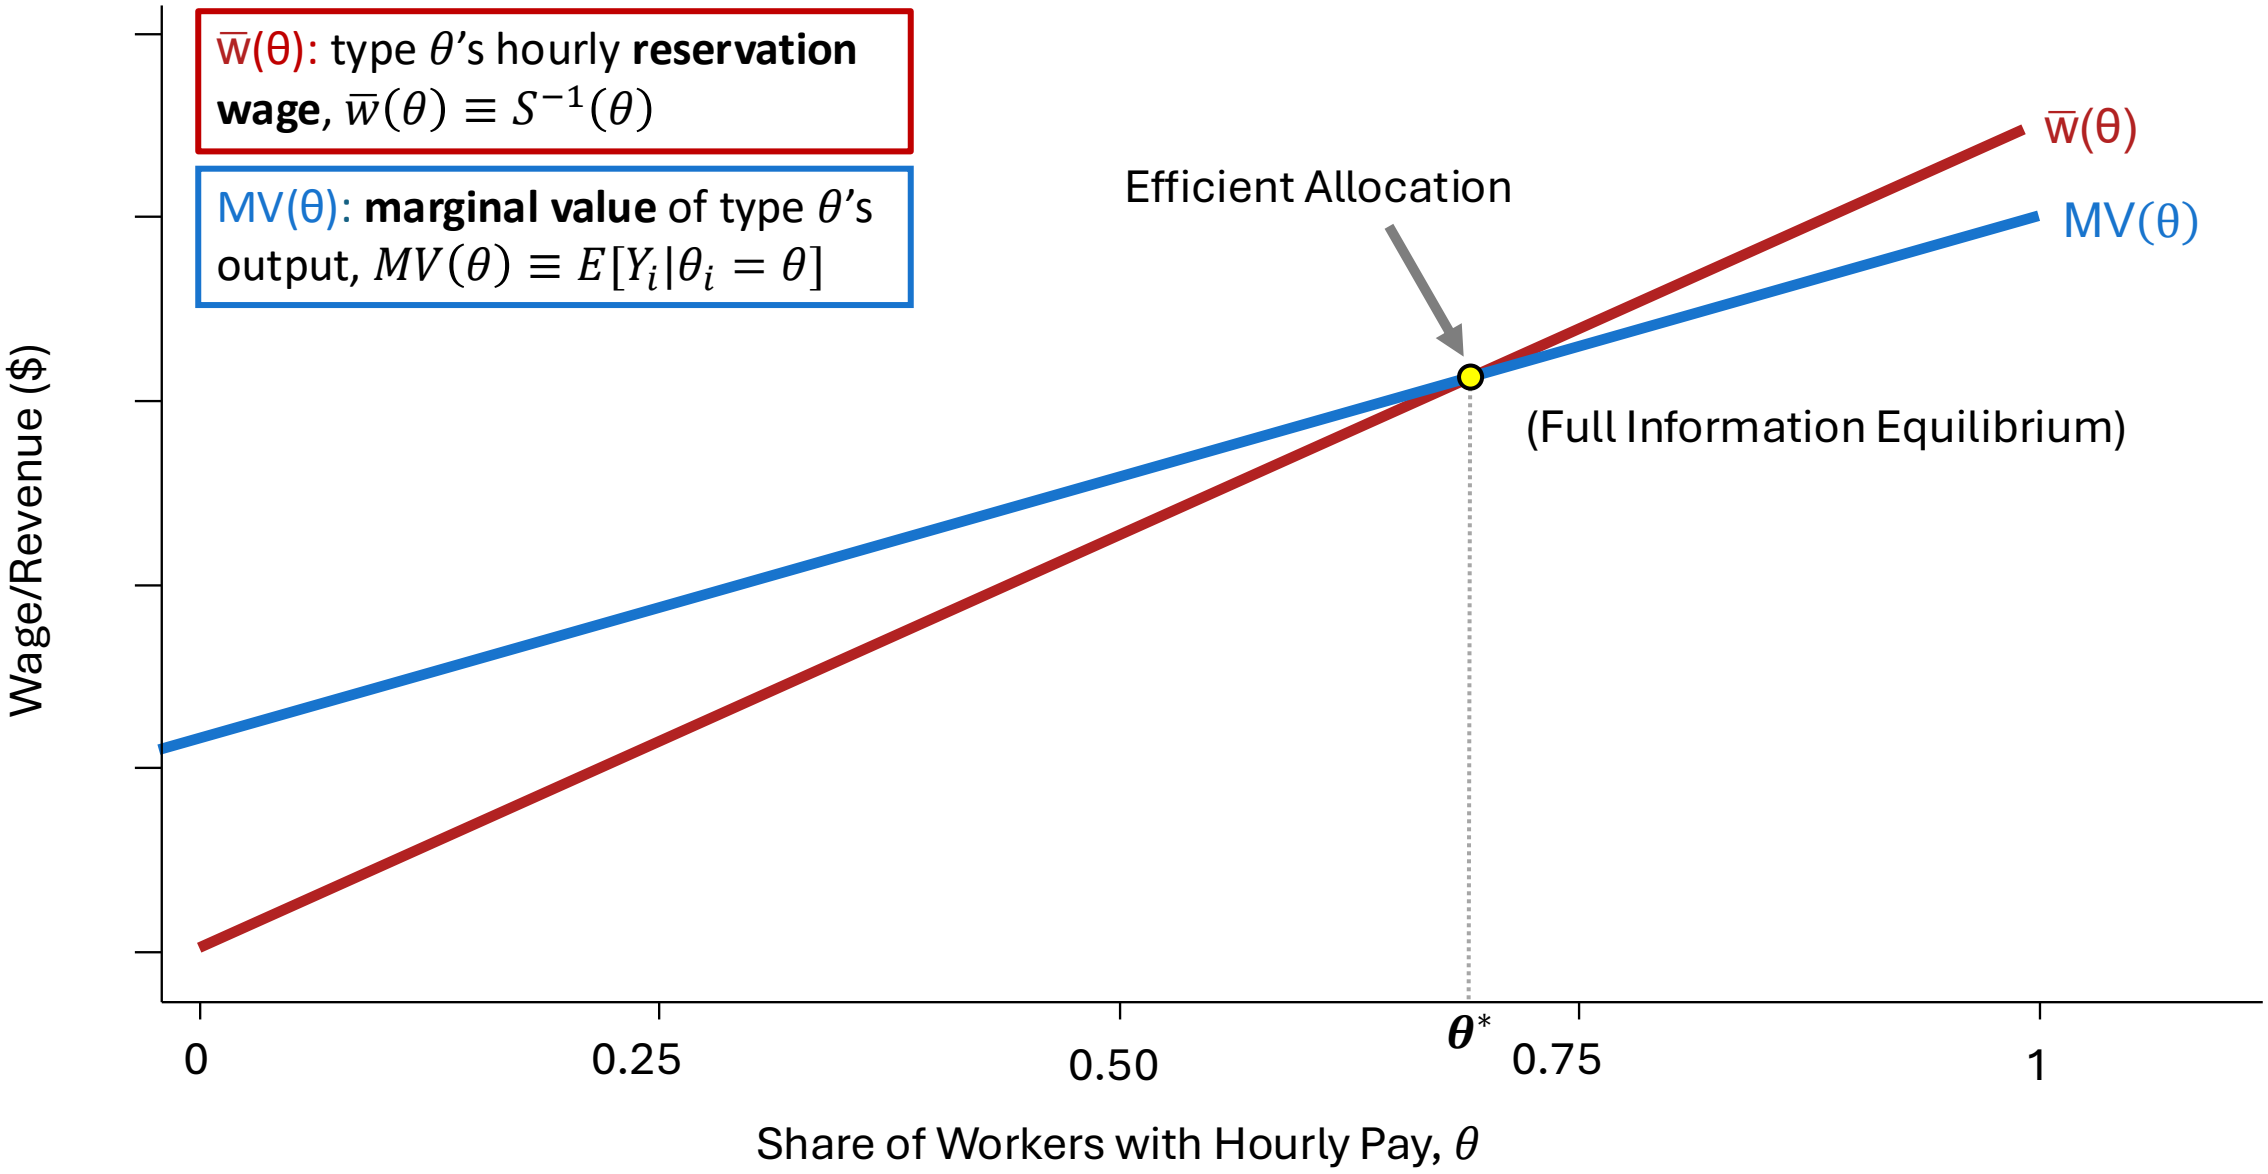

Each worker has reservation wage, $\overline{w}_i$, for hourly position
⇒ Supply of hourly workers, $S(w) \equiv \Pr(\overline{w}_i \leq w)$

Incorporating Moral Hazard

- Where does moral hazard fit in? Consider potential outputs

  Y_{1i}: Potential output value under hourly wage
  Y_{0i}: Potential output value under piece rate
  $\Big\}\ Y_{1i} = Y_{0i} + MH_i$

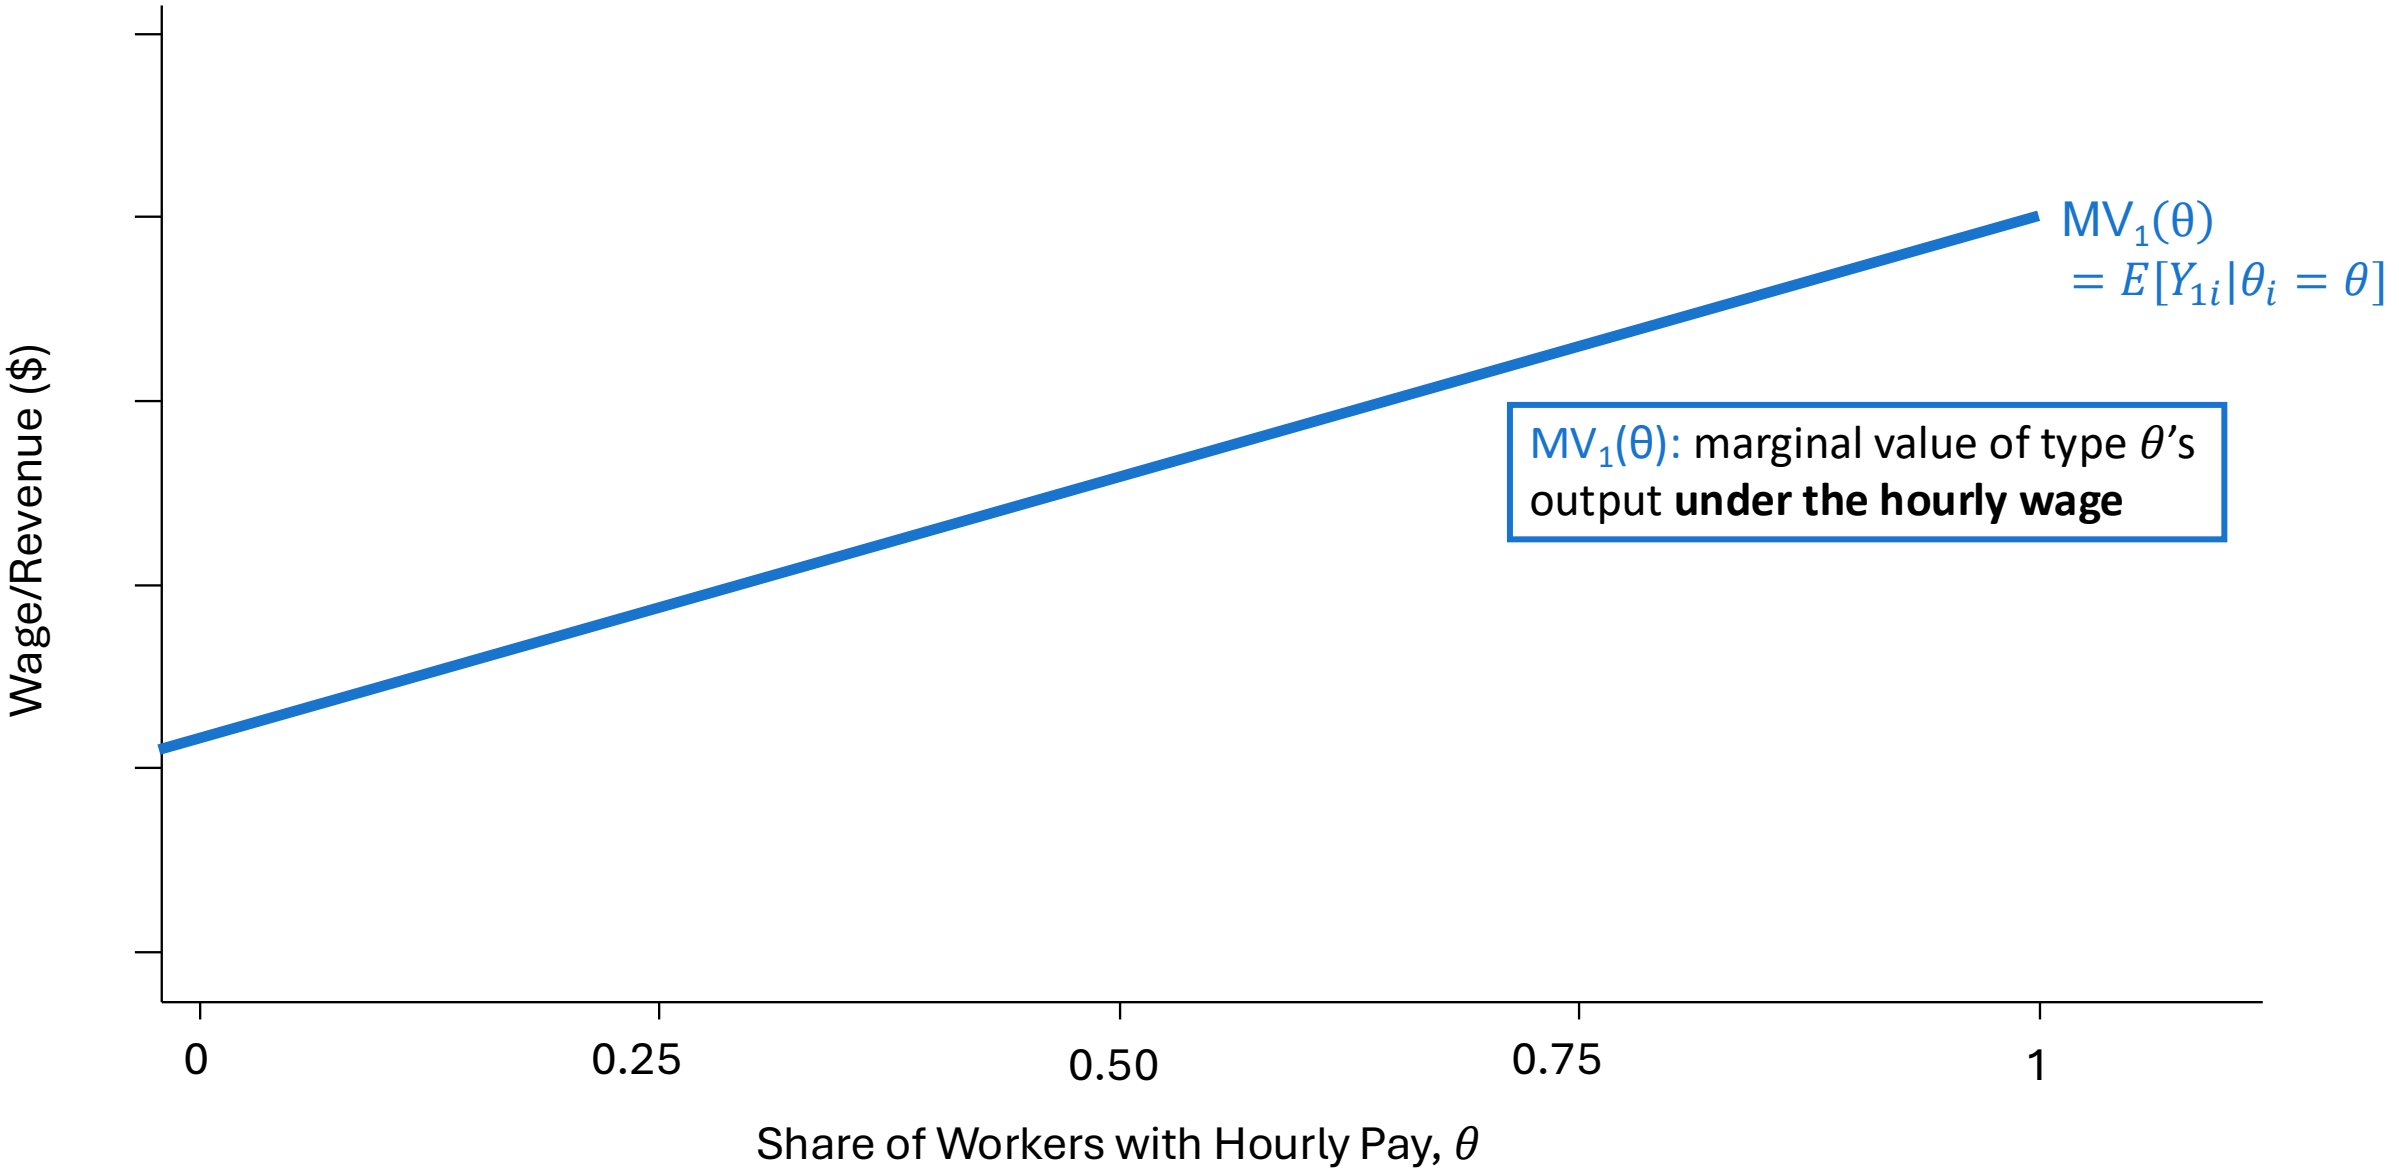

- Firms care about Y_{1i}, but they don't care about Y_{0i}
  - Piece-rate workers sell their output at a constant price per unit, so their productivity has no effect on firm profits
- $MV(\theta)$ & $AV(\theta)$ are defined *conditional* on accepting the hourly wage

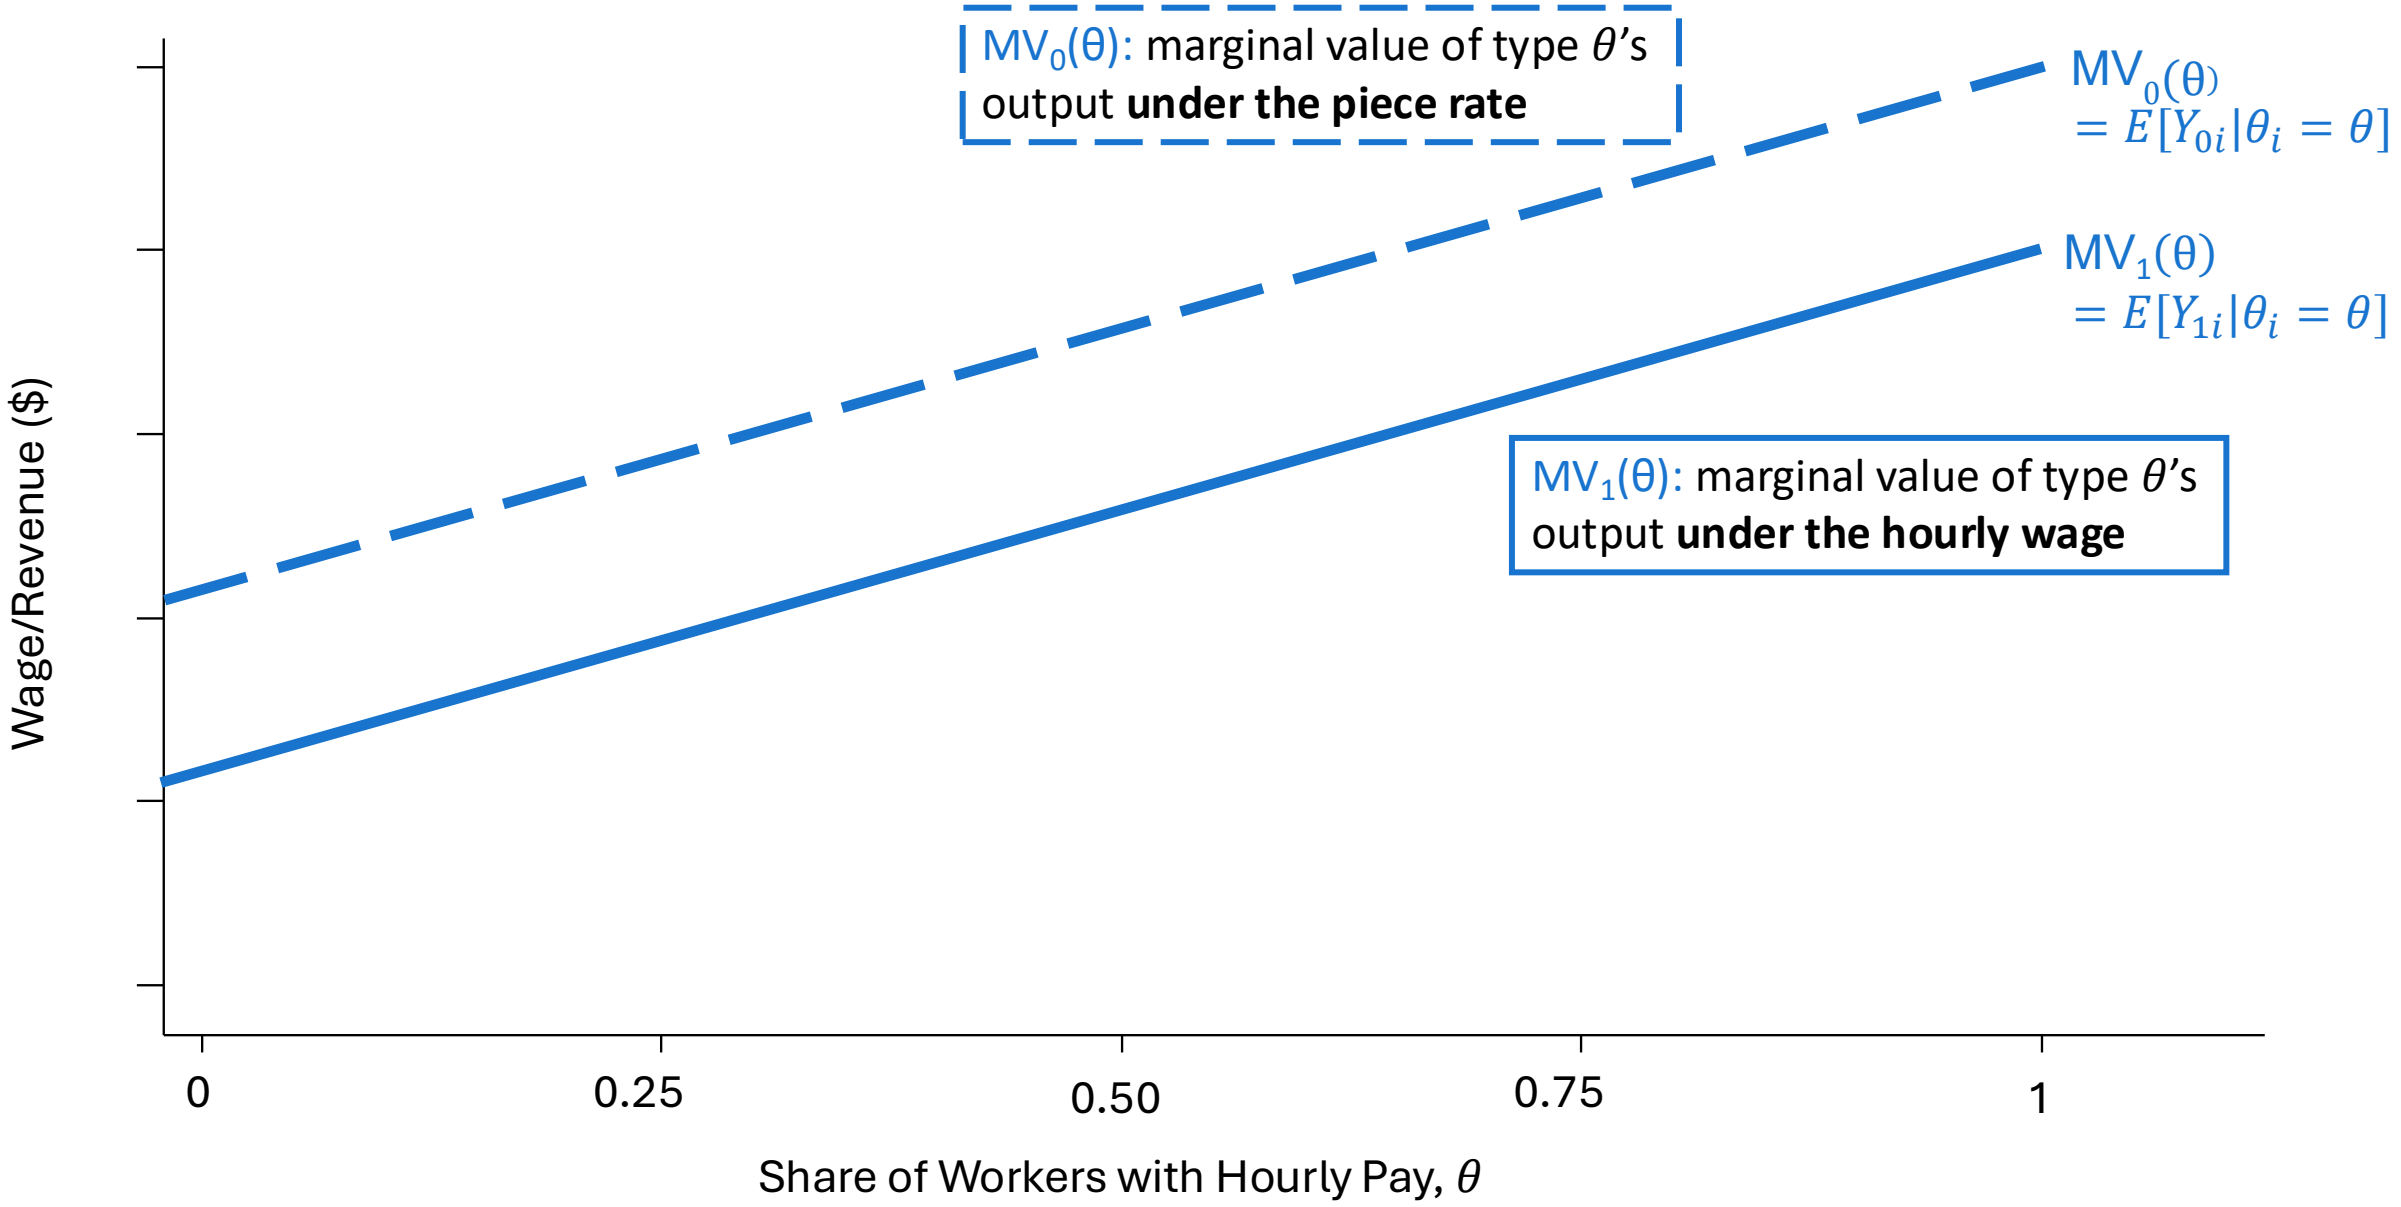

$$MV(\theta) \equiv E[Y_i|\theta_i = \theta] = E[Y_{1i}|\theta_i = \theta]$$
$$AV(\theta) \equiv E[Y_i|\theta_i \leq \theta] = E[Y_{1i}|\theta_i \leq \theta]$$

  ⇒ Equilibrium is inclusive of workers' moral hazard response to the hourly wage

- Still want to separately identify moral hazard
  - Firms might mitigate MH with "partial insurance" (e.g., sales commission, tips)
  - MH needed to measure welfare impact of policies promoting fixed-wages
    - Trade-off between insurance value and fiscal externality (MH ⇒ tax revenue ↓)

Policy Solutions

- Should government implement policies to encourage fixed wage contracts?
  - + Welfare benefit to marginal fixed-wage worker
  - – Fiscal cost from inducing that worker to shirk
- I calculate the **Marginal Value of Public Funds (MVPF)** for piece-rate tax

$$MVPF = \frac{Welfare\ Benefit}{Net\ Govt\ Expenditure}$$

Policy Solutions

- Should government implement policies to encourage fixed wage contracts?
  - + Welfare benefit to marginal fixed-wage worker
  - – Fiscal cost from inducing that worker to shirk

- I calculate the **Marginal Value of Public Funds (MVPF)** for piece-rate tax

$$MCPF = \frac{Welfare\ Loss}{Net\ Govt\ Revenue}$$

- MVPF of revenue-raising policies ≈ Marginal *Cost* of Public Funds (MCPF)

Socially efficient tax ⇒ ***lower*** MCPF

Policy: Piece-rate Tax

Marginal Cost of Public Funds (MCPF) for a piece-rate tax:

$$MCPF_{tax} = \frac{Welfare\ Loss}{Net\ Govt\ Revenue}$$

$Welfare\ Loss$: The aggregate amount workers would pay to avoid the tax

$Net\ Govt\ Revenue$: The aggregate revenue raised including fiscal externalities

Policy: Piece-rate Tax

Marginal Cost of Public Funds (MCPF) for a piece-rate tax:

$$MCPF_{tax} = \frac{Transfer - Insurance\ Value}{Net\ Govt\ Revenue}$$

$Welfare\ Loss$: The aggregate amount workers would pay to avoid the tax

- $Transfer$ from piece-rate employers to government
- $Insurance\ Value$ to workers who move from piece-rate to hourly pay

$Net\ Govt\ Revenue$: The aggregate revenue raised including fiscal externalities

Policy: Piece-rate Tax

Marginal Cost of Public Funds (MCPF) for a piece-rate tax:

$$MCPF_{tax} = \frac{Transfer - Insurance\ Value}{Transfer - Tax\ Loss\ from\ MH}$$

$Welfare\ Loss$: The aggregate amount workers would pay to avoid the tax

- $Transfer$ from piece-rate employers to government
- $Insurance\ Value$ to workers who move from piece-rate to hourly pay

$Net\ Govt\ Revenue$: The aggregate revenue raised including fiscal externalities

- $Transfer$ from piece-rate employers to government
- $Tax\ Loss\ from\ MH$ when hourly workers shirk and pay less income tax

Subsidy

Policy: Piece-rate Tax

Marginal Cost of Public Funds (MCPF) for a piece-rate tax:

$$MCPF_{tax} = \frac{\int_{\theta^{\rho}}^{1} \rho MV_0(\theta)d\theta - \int_{\theta^{EQ}}^{\theta^{\rho}} \left(MV_1(\theta) - \bar{w}(\theta)\right)d\theta}{\int_{\theta^{\rho}}^{1} \rho MV_0(\theta)d\theta + \int_{\theta^{EQ}}^{\theta^{\rho}} \frac{\tau}{1-\tau} MH(\theta)d\theta}$$

$Welfare\ Loss$: The aggregate amount workers would pay to avoid the tax

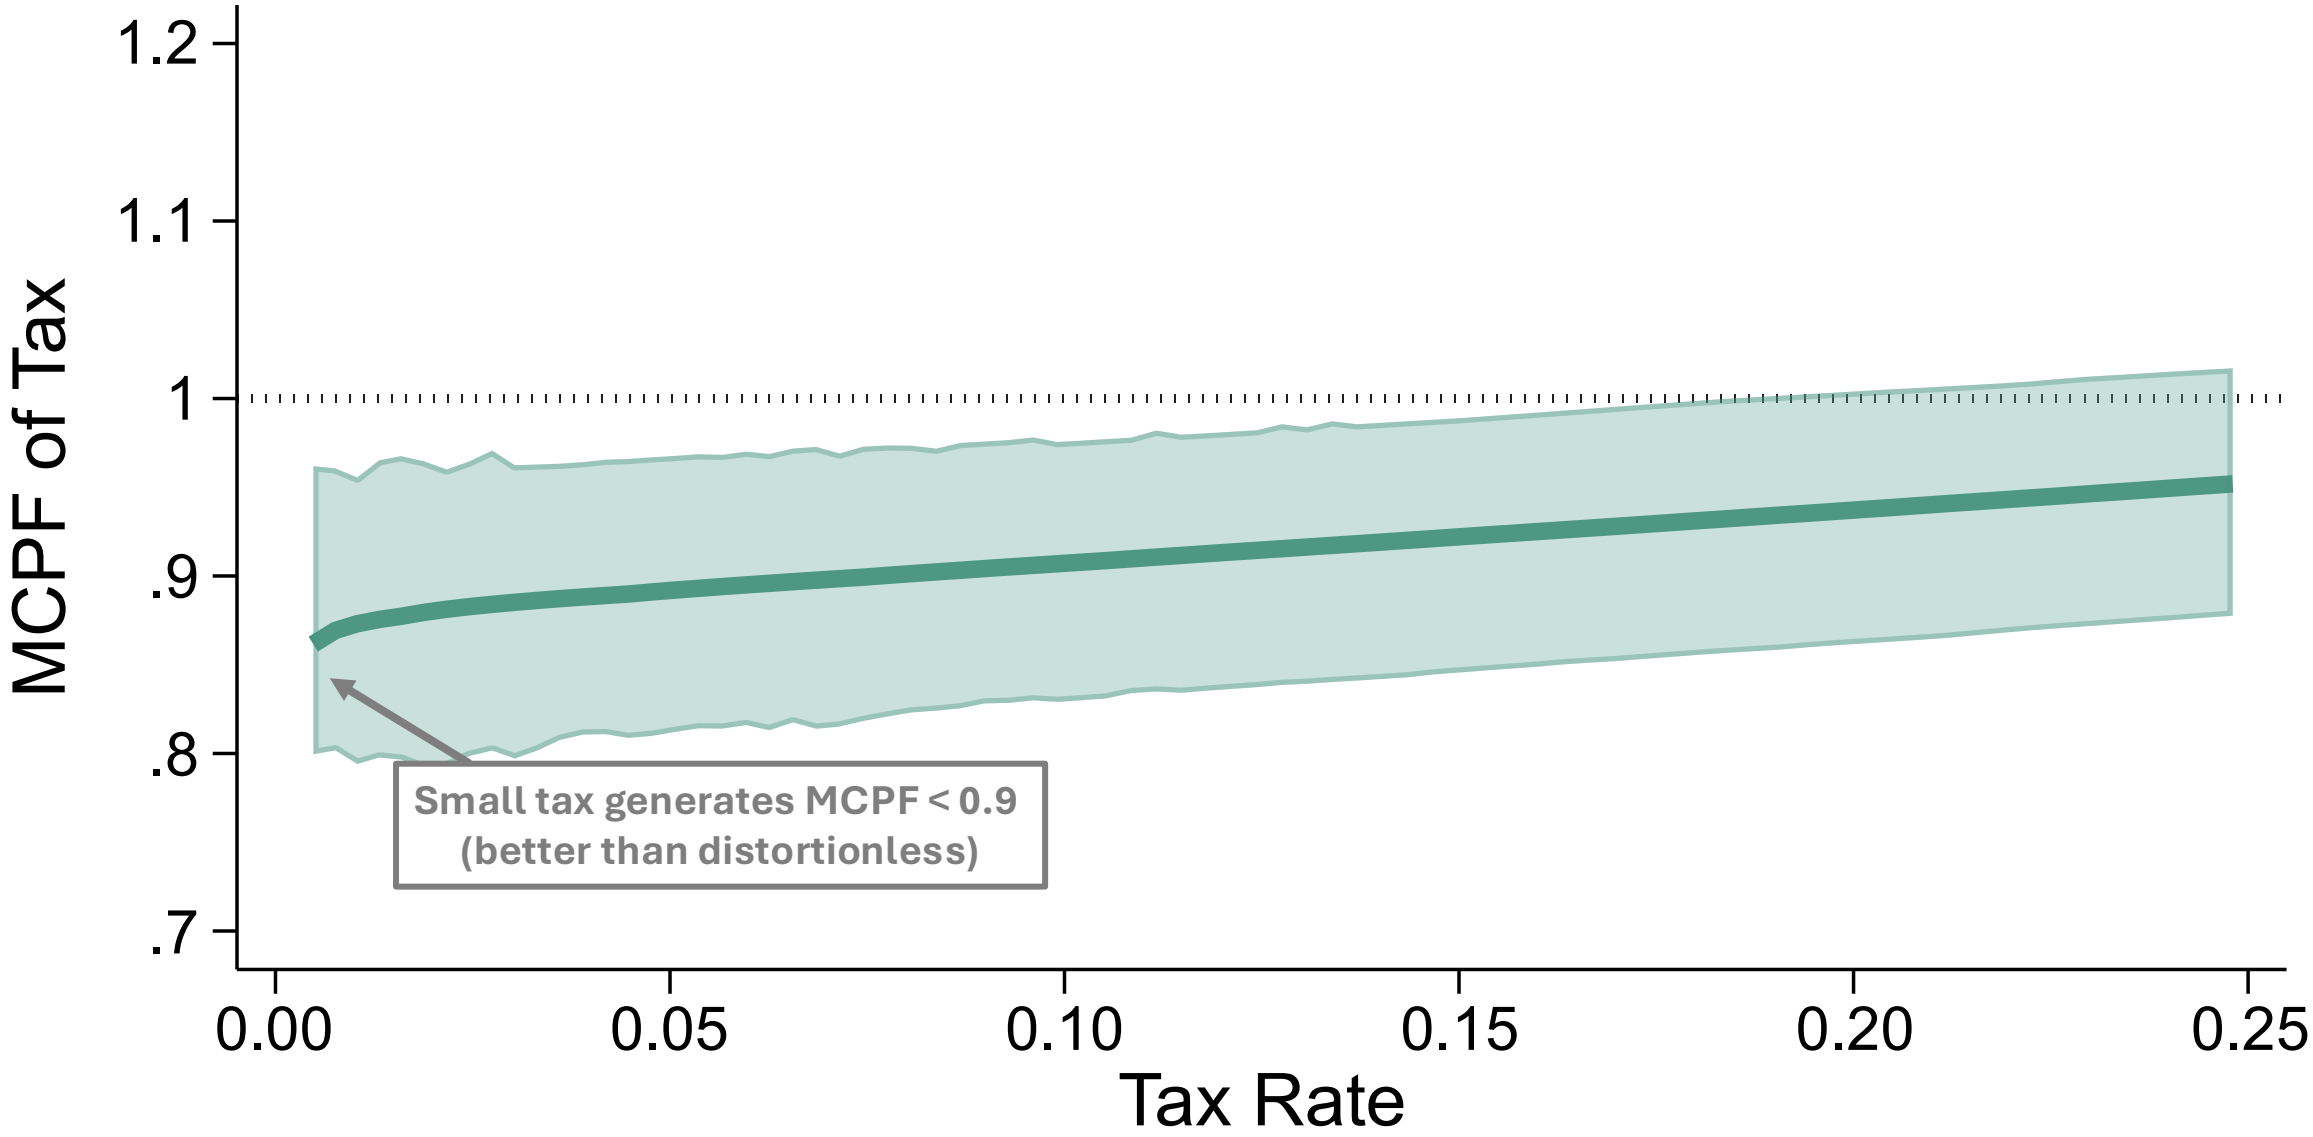

- $Transfer$ from piece-rate employers to government
- $Insurance\ Value$ to workers who move from piece-rate to hourly pay

$Net\ Govt\ Revenue$: The aggregate revenue raised including fiscal externalities

- $Transfer$ from piece-rate employers to government
- $Tax\ Loss\ from\ MH$ when hourly workers shirk and pay less income tax

Generalizing to Other Labor Markets

- Results are specific to online workers performing a data-entry task.
- Division of labor ⇒ applied research on worker incentives usually comes from highly specialized settings
  - Rideshare drivers (Angrist et al., 2021; Cook et al., 2021)
  - Agricultural workers (Brune et al., 2022; Bandiera et al., 2010)
  - Cashiers (Mas and Moretti 2009)
  - Windshield repair (Lazear 2000)
  - Call centers (Mas and Pallais 2017; Nagin et al. 2002)
- Even so, I try to make the experimental task as generalizable as possible
  - 66% of US workers type on the job
  - Workers don't know it's an experiment (debriefed afterwards)
- Methods can be applied elsewhere, especially short-term labor markets

Extensions: Why do these jobs have unpredictable pay?

Having full-time contractual employment does come with some certainty. You know you have an income every month…Now who knows?

– Skhumbuzo Ngubo, Uber Driver

Application to Rideshare Drivers (Angrist et al., 2021)

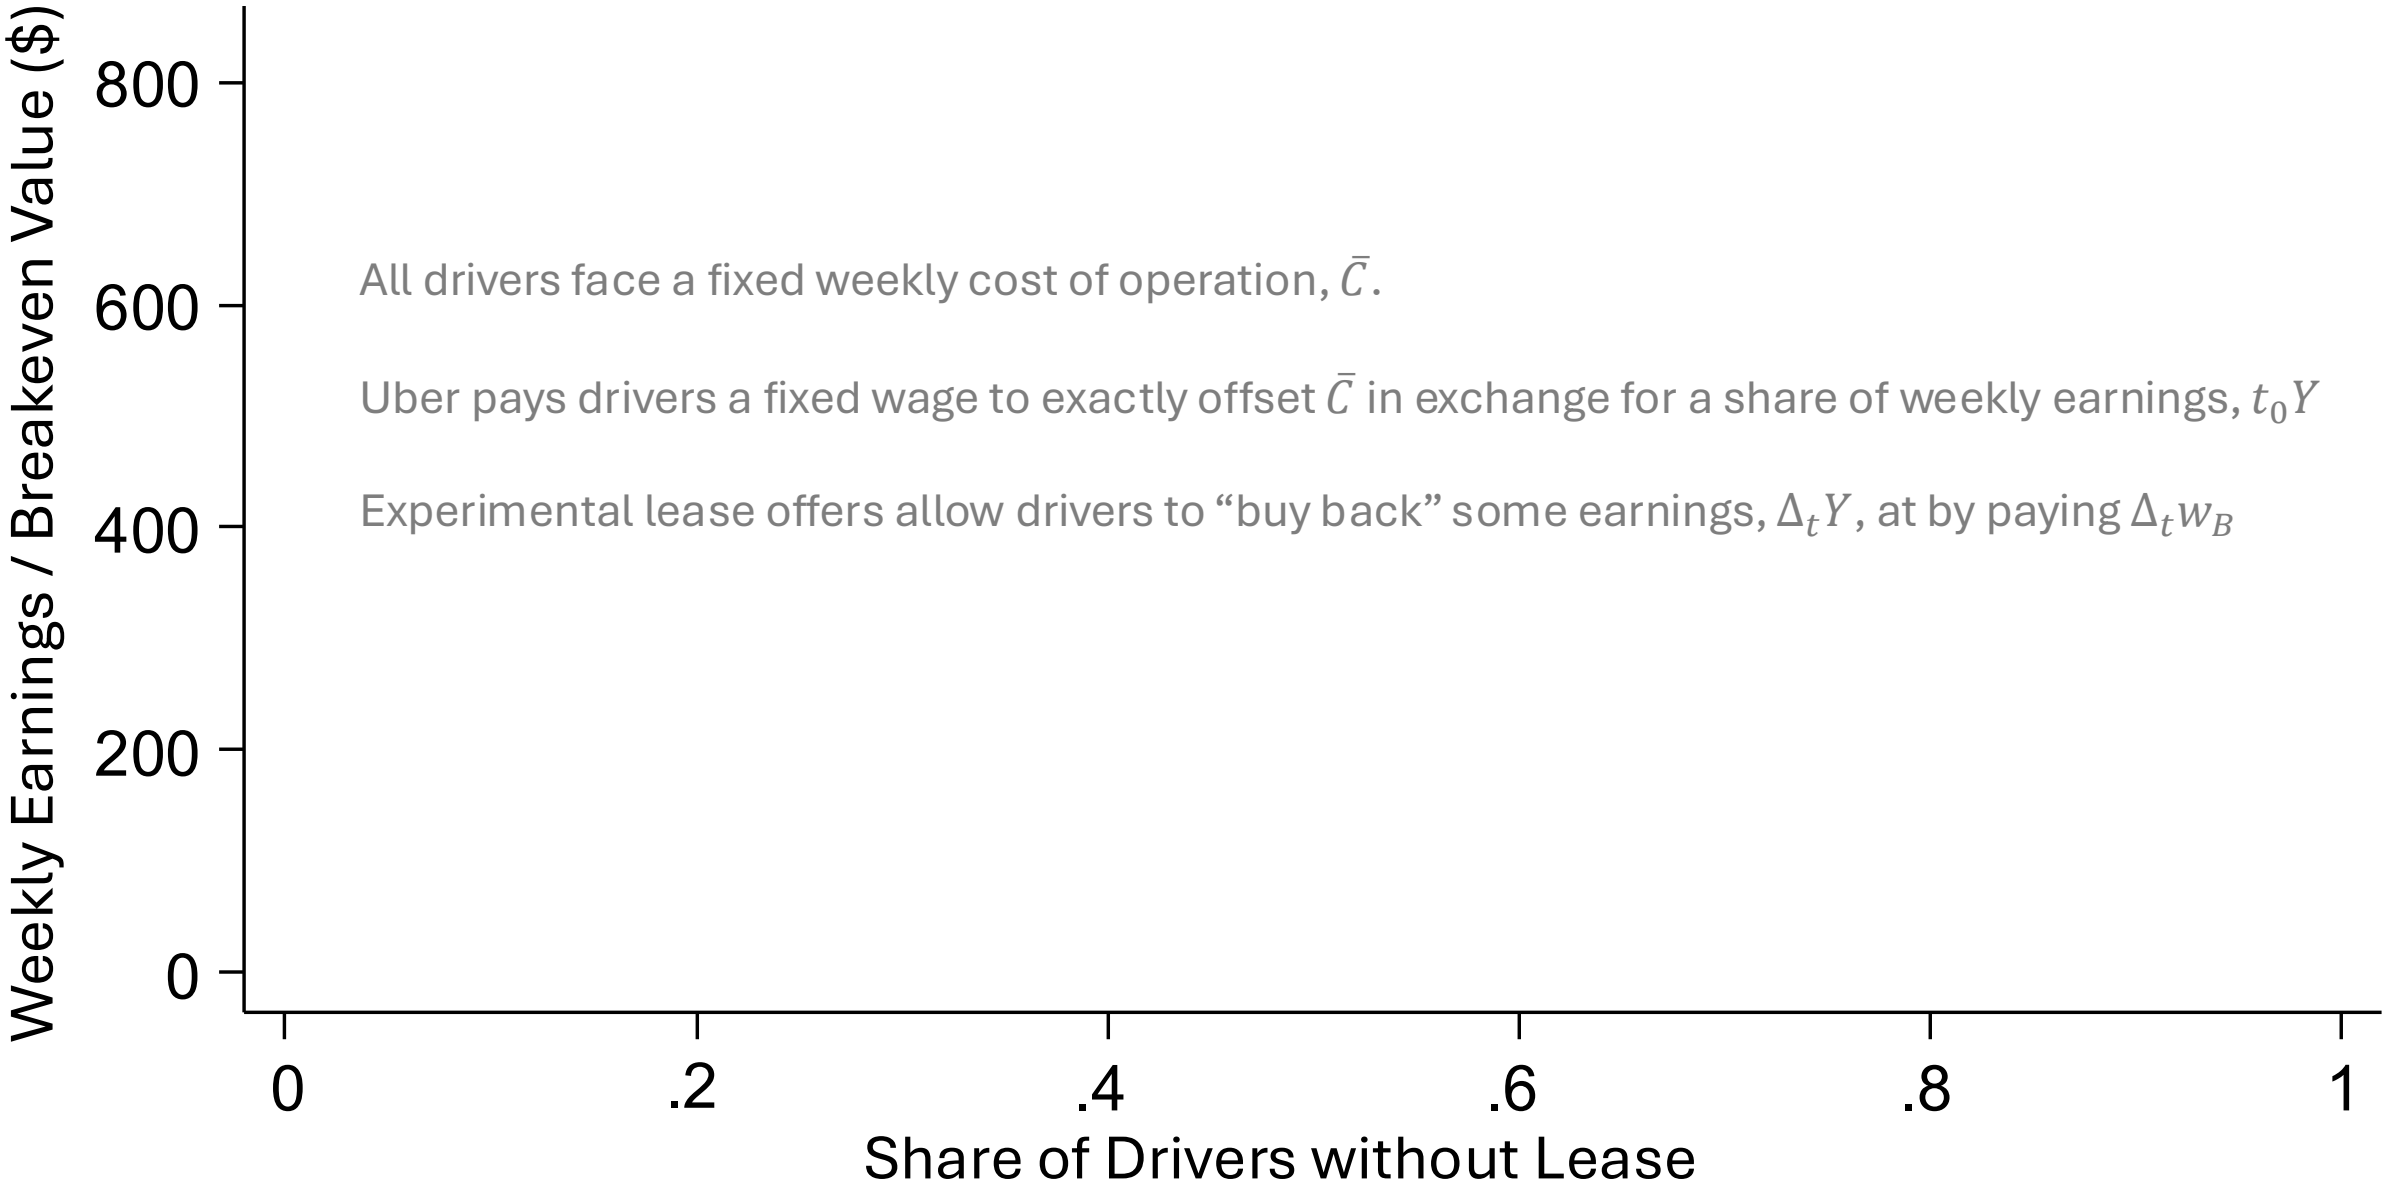

- RCT offers drivers larger commissions on ride fares in exchange for fixed "taxi-style" lease payments

  ⇒ Driver can "buy back" some labor product

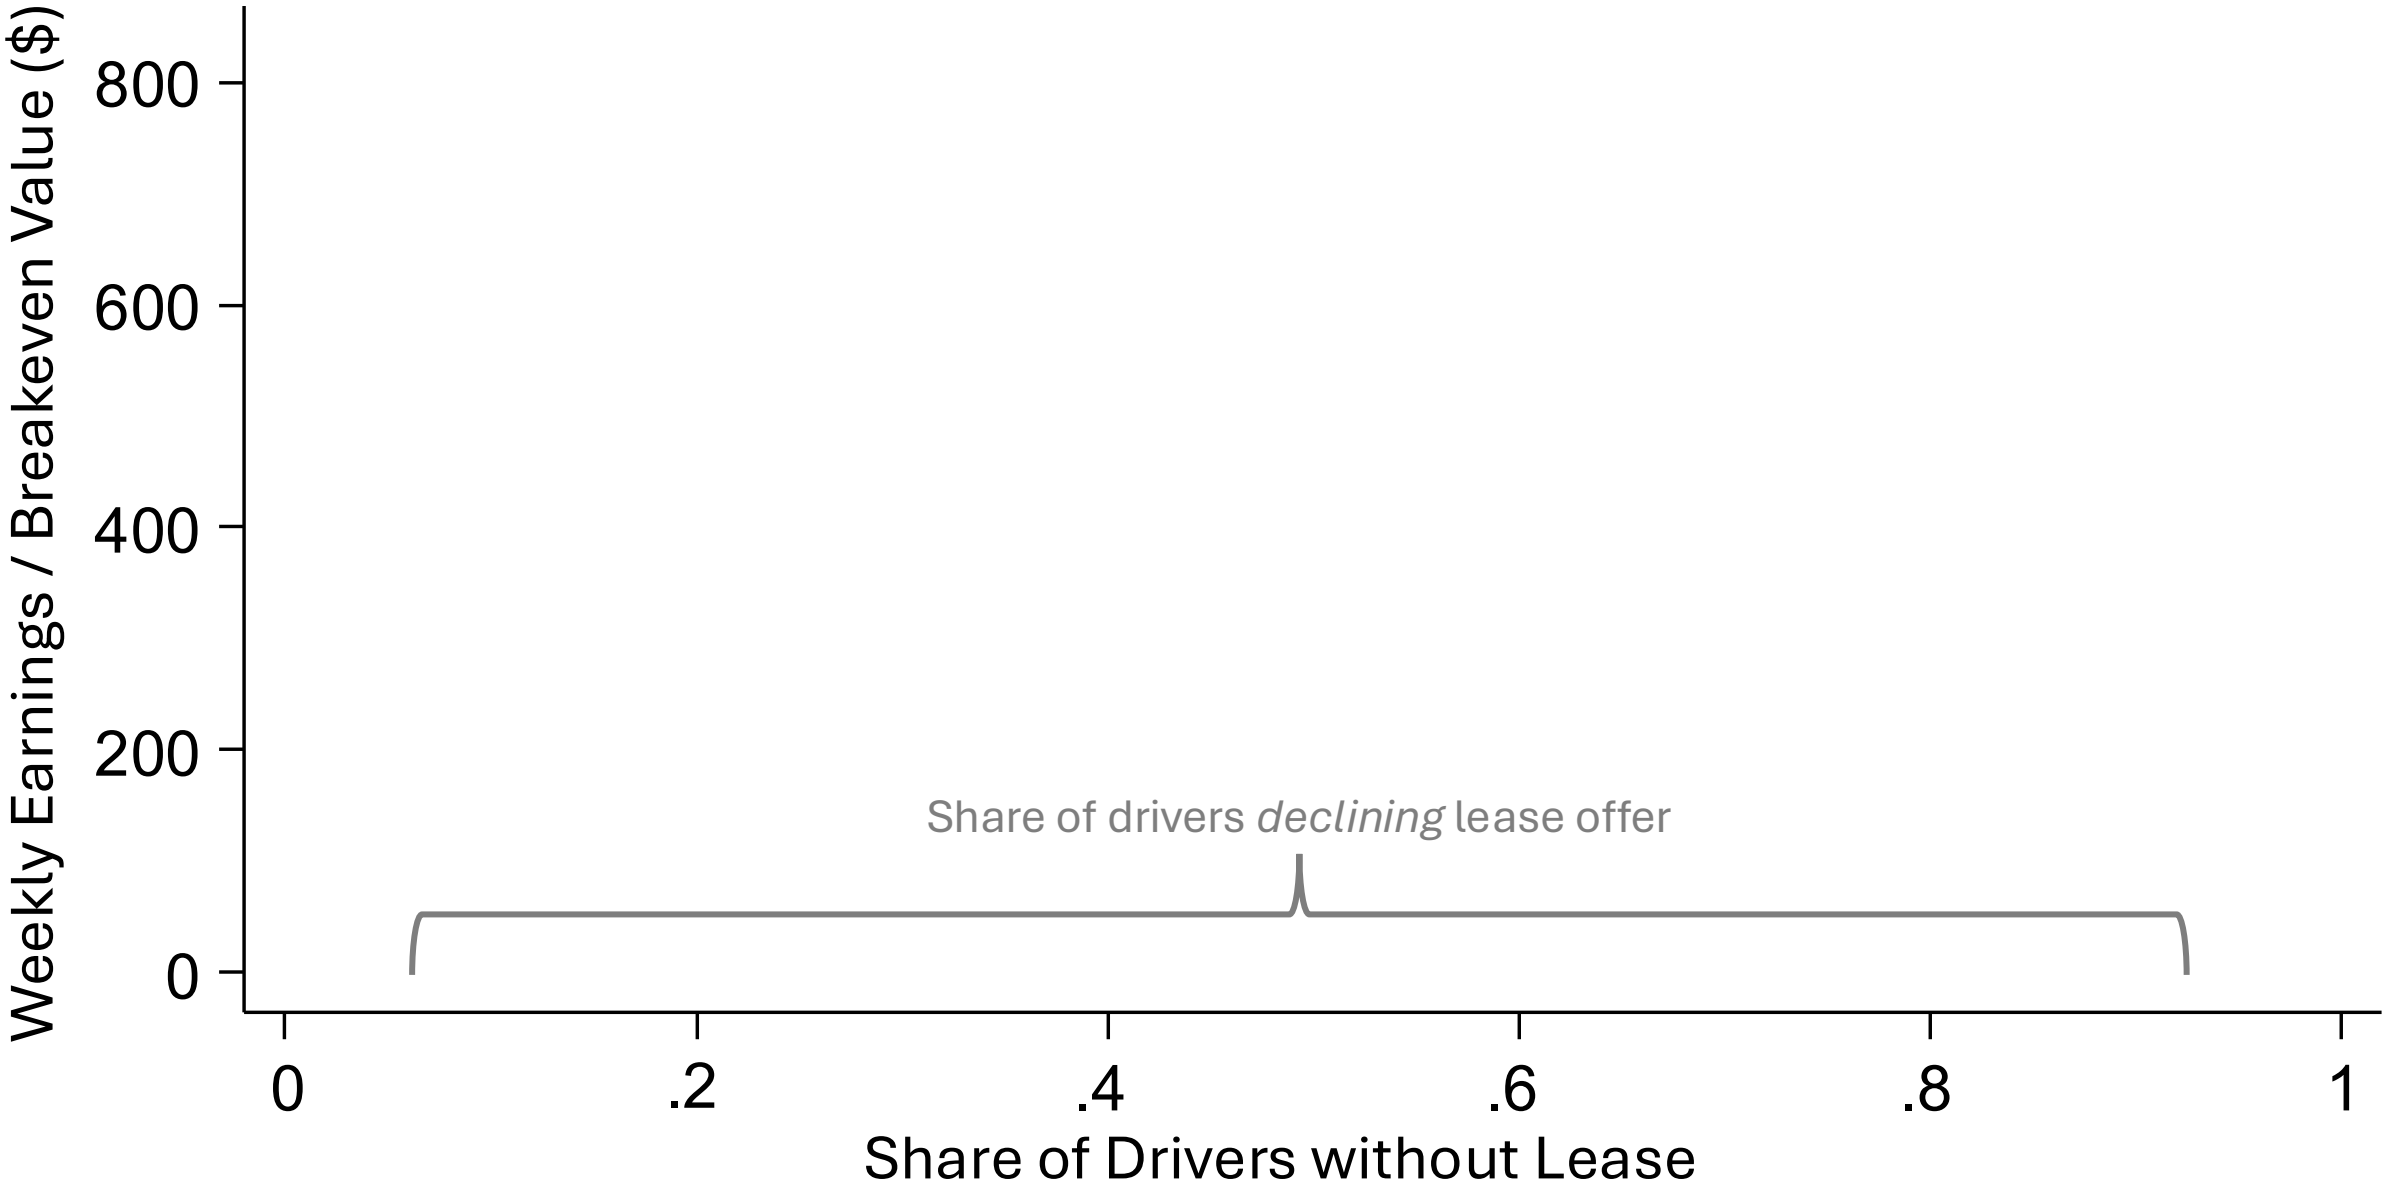

- Fixed-wage option ≈ "lease-free" driving (i.e., *decline* taxi offer)

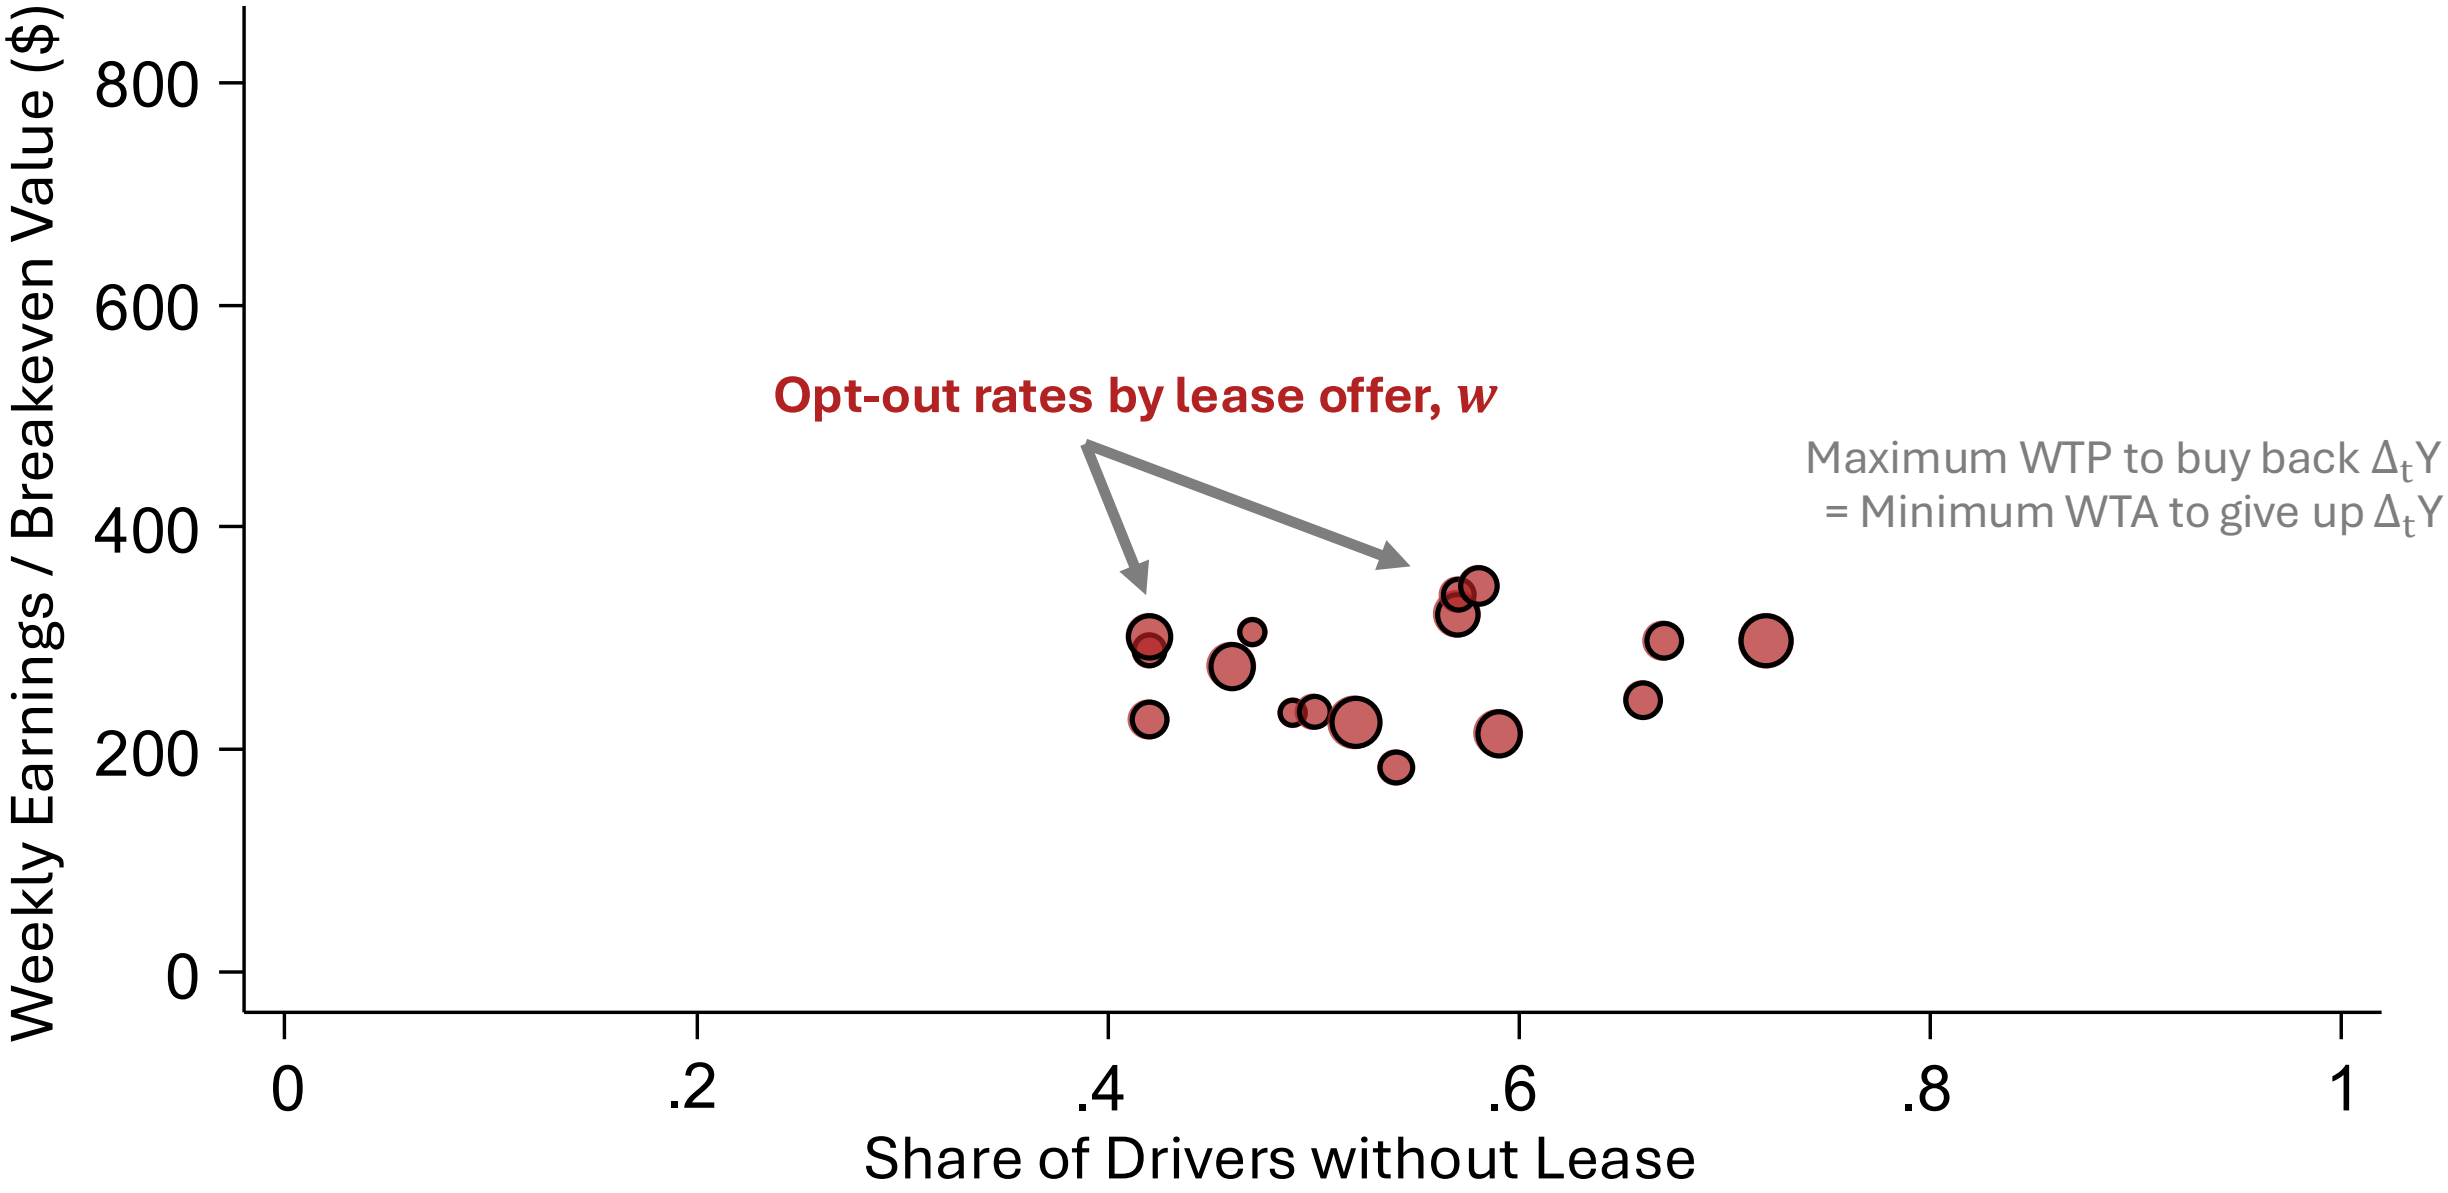

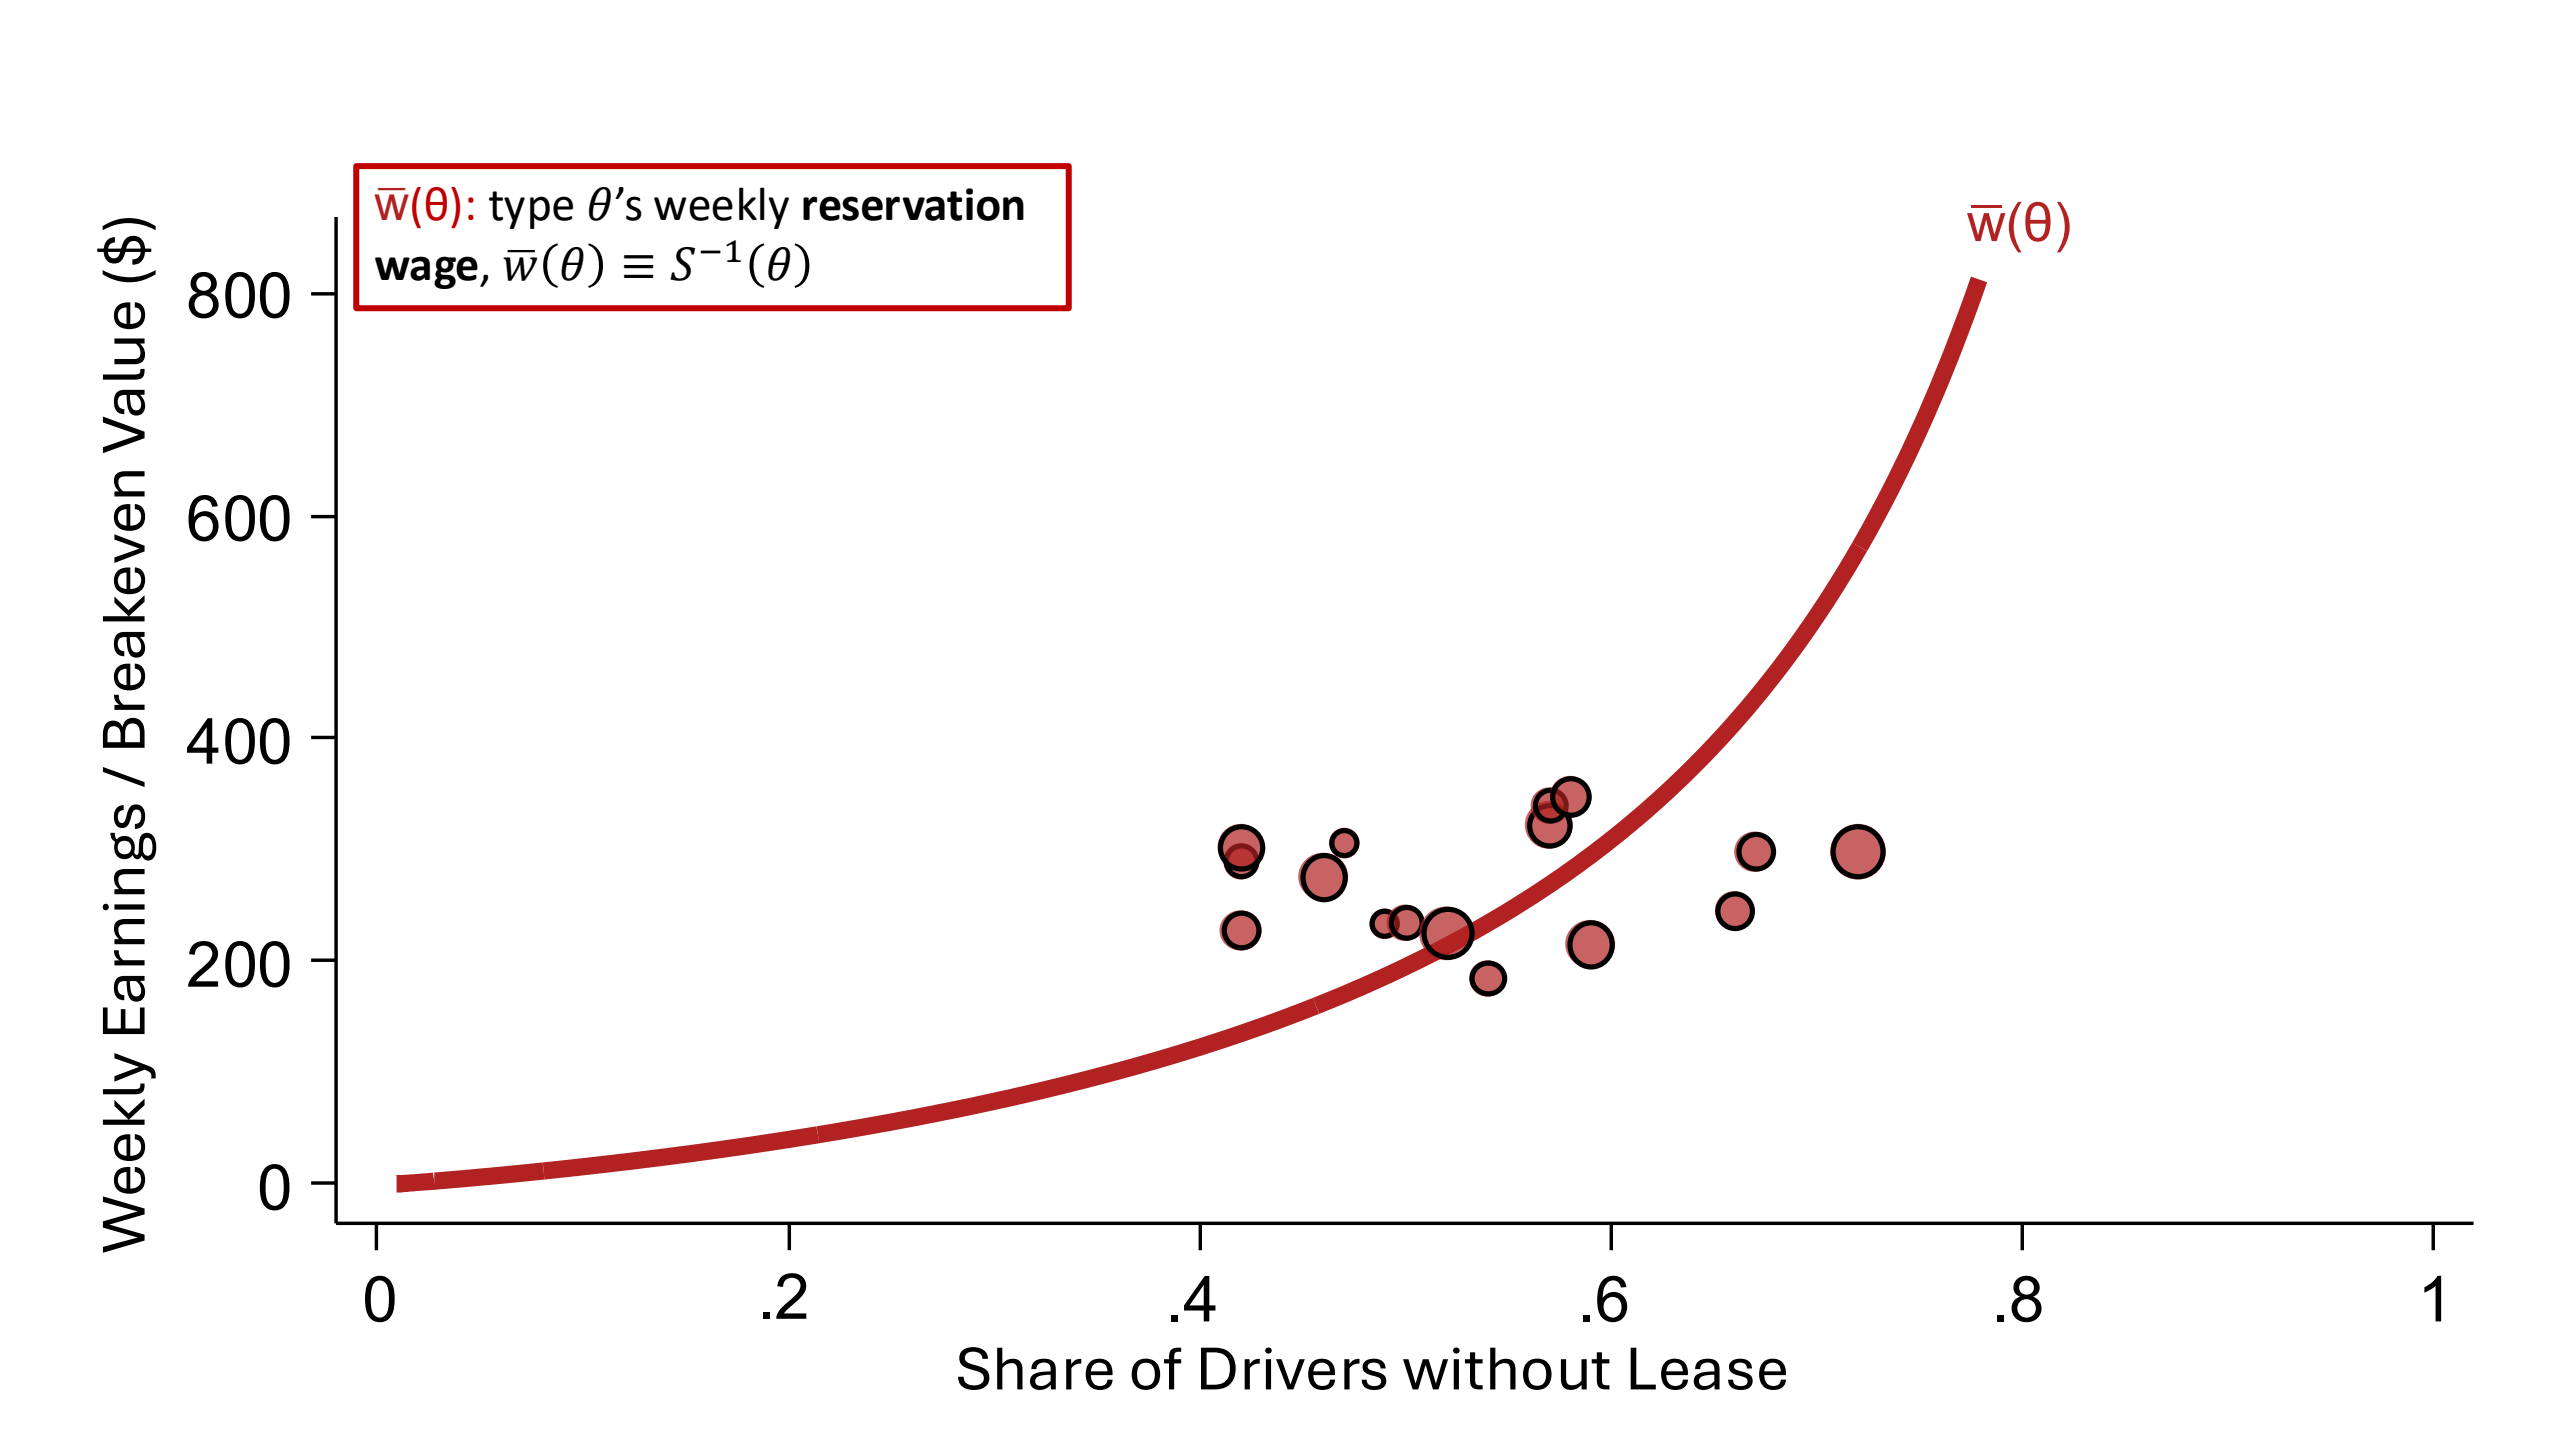

- Evidence of moral hazard and adverse selection
  - MH: lease take-up increases labor supply (ISE = 1.2)
  - AS: more productive drivers have higher WTP for leases ($\Delta_{Y_0} = \$21$)
- AS+MH ⇒ over-reliance on commissions? Welfare implications?
  - Calibrate my model using estimates from Angrist et al. (2021)

All drivers face a fixed weekly cost of operation, $\bar{C}$.
Uber pays drivers a fixed wage to exactly offset $\bar{C}$ in exchange for a share of weekly earnings, $t_0 Y$
Experimental lease offers allow drivers to "buy back" some earnings, $\Delta_t Y$, at by paying $\Delta_t w_B$

Tax Rate

Application to Rideshare Drivers

- Findings
  - Sub-optimal equilibrium relies heavily on unpredictable fares.
  - Welfare loss of $1.32 per week driven.
  - Taxing fare-based compensation mitigates adverse selection
  - Can generate government revenue at with minimal social welfare costs.
- Limitations
  - Linear extrapolation
  - Experimental sample consists of *existing* Uber drivers.
  - Excludes drivers with highest $\overline{w}$—they're already working as taxi drivers!

[After eliminating tips, server positions] have been harder to fill. Many veteran servers weren't interested, saying they could make double elsewhere with tips…As a result, many of the people who work in the dining room started with little to no restaurant experience.

–Owner, Liholiho Yacht Club

Conclusion

- Experimental and theoretical framework for asymmetric information in wage contracts
  - Shows how moral hazard and adverse selection affect market equilibrium and welfare
  - Model correspondence to MTE estimands ⇒ semi-parametric identification

- Apply framework to data-entry workers using an RCT that varies wage *offers*
  - Results imply an underprovision of fixed-wage contracts

- Policy prescription: increase taxes on piece-rate compensation (e.g., tips?)
  - $\tau \leq 19\%$ raises \$1 of government revenue at an estimated social cost of \$0.88 or less

- Extensions: use framework to estimate welfare loss in other markets
  - Experimentally vary compensation offers for other types of work (e.g., rideshare drivers)
  - Alternatively, use linked survey + administrative wage/productivity data

Conclusion

- Experimental and theoretical framework for asymmetric information in wage contracts
  - Shows how moral hazard and adverse selection affect market equilibrium and welfare
  - Model correspondence to MTE estimands ⇒ semi-parametric identification

- Apply framework to data-entry workers using an RCT that varies wage *offers*
  - Results imply an underprovision of fixed-wage contracts

- Policy prescription: increase taxes on piece-rate compensation (e.g., tips?)
  - $\tau \leq 19\%$ raises \$1 of government revenue at an estimated social cost of \$0.88 or less

- Extensions: use framework to estimate welfare loss in other markets
  - Experimentally vary compensation offers for other types of work (e.g., rideshare drivers)
  - Alternatively, use linked survey + administrative wage/productivity data

Any outcome-contingent contract can be vulnerable to moral hazard and adverse selection!

Thank you!

Detecting Moral Hazard and Adverse Selection

Existing methods of testing for moral hazard and adverse selection:

1. Test for correlation between take-up and realized risk (Chiappori and Salanie 2000)
   - Cannot separate adverse selection from moral hazard
2. Compare take-up and risk across exogenous price changes in existing markets (Einav et al. 2010, Einav et al. 2013; Hackmann et al. 2012)
   - "Under-the-lamppost" problem: Cannot observe *unraveled* contracts, which are unprofitable
3. Construct *hypothetical* contract choices from surveys on subjective beliefs (Herbst and Hendren 2024; Hendren 2013, 2017)
   - Strong parametric assumptions to predict choices across "missing" contracts

Detecting Moral Hazard and Adverse Selection

Existing methods of testing for moral hazard and adverse selection:

1. Test for correlation between take-up and realized risk (Chiappori and Salanie 2000)
   - Cannot separate adverse selection from moral hazard
2. Compare take-up and risk across exogenous price changes in existing markets (Einav et al. 2010, Einav et al. 2013; Hackmann et al. 2012)
   - "Under-the-lamppost" problem: Cannot observe *unraveled* contracts, which are unprofitable
3. Construct *hypothetical* contract choices from surveys on subjective beliefs (Herbst and Hendren 2024; Hendren 2013, 2017)
   - Strong parametric assumptions to predict choices across "missing" contracts

My strategy: if I can't observe missing contracts, offer them myself!

- Advantage #1: I can experimentally randomize contract prices (i.e., wages)
- Advantage #2: I can offer unraveled (i.e., unprofitable) contracts

Experimental Design: Single Wage Offer

Comparing piece-rate workers who faced different offer sets identifies ***selection into treatment:***

$$\frac{E[Y_i|W_i=0]-E[Y_i|H_i=0,W_i=1]}{\pi}=\frac{(\pi E[Y_{0i}|H_i=1]+(1-\pi)E[Y_{0i}|H_i=0])-E[Y_{0i}|H_i=0]}{\pi}=E[Y_{0i}|H_i=1]\ -E[Y_{0i}|H_i=0]$$

Back

Identifying Selection Across Multiple Wage Offers

W_i: Randomized treatment-offer group

- $W_i = L$: Offered a choice between low hourly wage and piece rate
- $W_i = H$: Offered a choice between high hourly wage and piece rate
- π^W: Take-up of wage offer $W \in \{L, H\}$

Selection on Y_0 into offer H among those who would reject offer L:

$$E\left[Y_{0i} \middle| H_i^H = 1, H_i^L = 0\right] - E\left[Y_{0i} \middle| H_i^H = 0\right]$$

$$= \frac{1-\pi^L}{\pi^H - \pi^L} E[Y_i | H_i = 0, W_i = L] - E[Y_i | H_i = 0, W_i = H]$$

Selection on Y_1 into offer L among those who would accept offer H:

$$E\left[Y_{1i} \middle| H_i^L = 1\right] - E[Y_{1i} | H_i^H = 1, H_i^L = 0]$$

$$= \frac{\pi^H}{\pi^H - \pi^L} E[Y_i | H_i = 1, W_i = L] - E[Y_i | H_i = 1, W_i = H]$$

You will be shown a series of handwritten sentences. On each page, your task is to type the sentence into the text box below.

Here is one example of a completed sentence:

The quick brown fox jumps over the lazy dog.

Your answers should be as accurate as possible. Please be mindful of capitalization, spacing, and punctuation. When you've completed a sentence, click the "→" button to move on.

You will have 5 minutes to complete as many sentences as you can. You cannot start over, and you can only perform this task once.

→

Before you begin the task, we'd like to offer you a choice of how to earn your bonus payment. Please select your preferred bonus compensation from the options below:

Get paid a $0.03 bonus for each sentence you correctly complete.	Get paid a flat bonus of $1.00.
◉	○

Time Remaining: 05:00

For performing this task, you will receive **$1.00**, plus your chosen bonus of **$0.03 per correct sentence**.

Click "Begin Task" to begin your 5-minute typing task.

Once you begin, the timer will start. Do not press the back button or refresh your browser—doing so may invalidate your results!

N	2728	2728	2728	2728

$$\Pr(H_i = 1) = \text{inv logit}\left(\alpha \ln W_i + \boldsymbol{\nu X_i}\right)$$

Suppose supply and average value are linear in the wage offer:

$$Y_i = \xi_0 + \alpha H_i + \beta_0(1 - H_i)\times W_i + \beta_1 H_i \times W_i + \gamma H_i \times W_i^P + \epsilon_i$$
$$H_i = \gamma + \delta w + \nu_i$$

Let $\overline{w}_i$ be worker i's hourly reservation wage ⇒ CEFs of hourly take-up and output value:

$$\Pr(\overline{w}_i \leq w) = \gamma + \delta w$$
$$\mathrm{E}[Y_i|\overline{w}_i \leq w] = \xi_0 + \alpha + \beta_1 H_i \times w$$
$$\mathrm{E}[Y_i|\overline{w}_i > w] = \xi_0 + \beta_0(1 - H_i)\times w$$

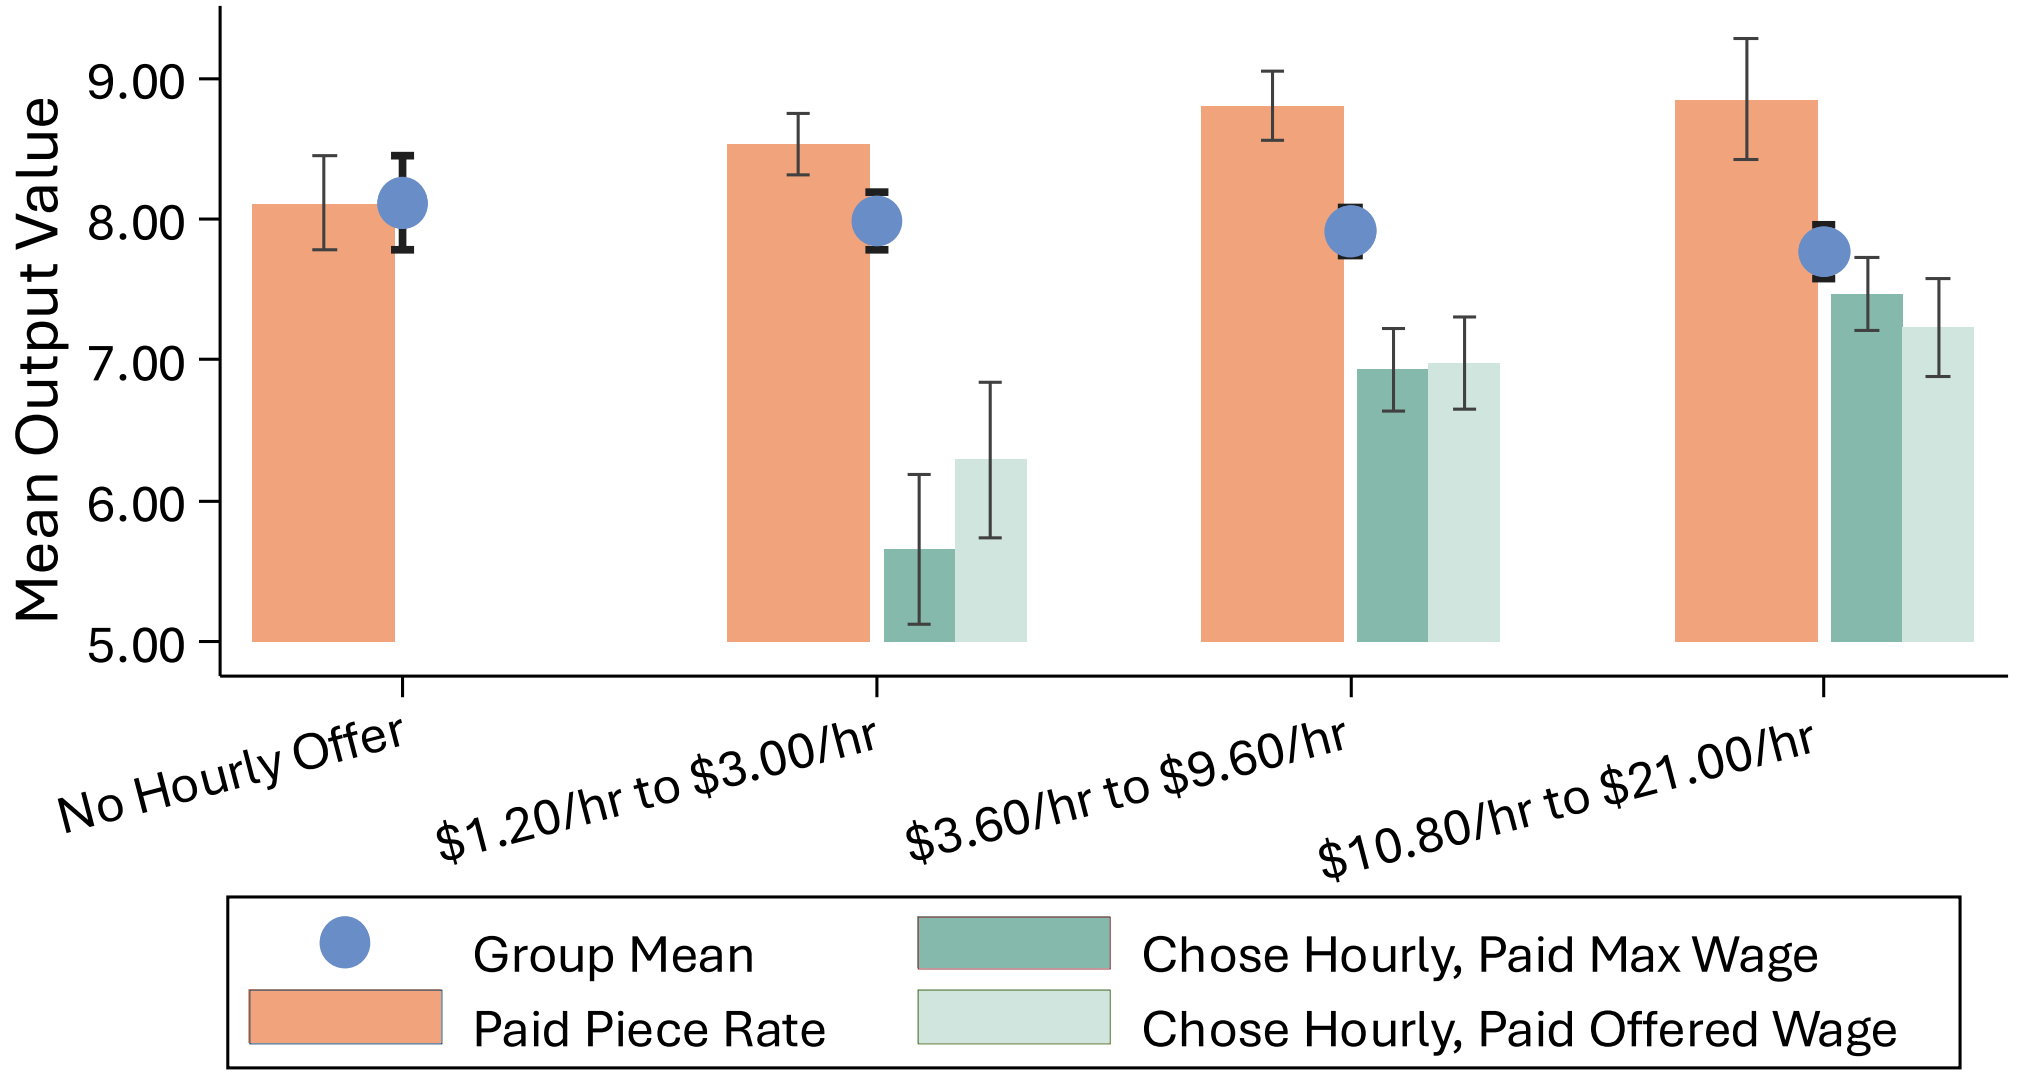

The *marginal* potential output values $E[Y_{1i}|\overline{w}_i = w]$ & $E[Y_{0i}|\overline{w}_i = w]$ are given by

$$E[Y_{1i}|\overline{w}_i = w] = \frac{\partial(\mathrm{E}[Y_i|\overline{w}_i \leq w]S(w))}{\partial S(w)} = \xi_0 + \alpha + \frac{\gamma\beta_1}{\delta} + 2\beta_1 w$$

$$E[Y_{0i}|\overline{w}_i = w] = -\frac{\partial\left(\mathrm{E}[Y_i|\overline{w}_i > w]\big(1 - S(w)\big)\right)}{\partial S(w)} = \xi_0 + \frac{(\gamma - 1)\beta_0}{\delta} + 2\beta_0 w$$

Estimation Details

Estimation Follows Carneiro et al. (2011):

1. Estimate $S(w) \equiv \Pr(H_i = 1 | W_i = w)$ using logit regression
2. Condition on X using double-residual regression (Robinson 1988)
   - X: Controls for number of previous tasks, task start time, and employment status
   - Assumes additive separability of X: $E\left[Y_{Ji} \middle| X_i = x, \theta_i = \theta\right] = \xi_J \tilde{X}_i + MV_J(\theta)$
3. Separately estimate $E[Y_i | S(W_i) = \theta, H_i = 1]$ and $E[Y_i | S(W_i) = \theta, H_i = 0]$
   - Local quadratic regressions of $\tilde{Y}$ on $S(W_i)$ for hourly and piece-rate workers (bw=0.2)
4. Differentiate with respect to θ
